Purpose: The SNARE complex facilitates fusion of vesicular cargo to a target membrane. Syntaxin 3 (Stx3) has been implicated in trafficking of proteins to the photoreceptor outer segment and exocytosis of synaptic vesicles. Previously, we found that stxbp1b and stx3 were essential for photoreceptor morphogenesis and survival in zebrafish. The purpose of this study was to further investigate the roles of Stx3 and Stxbp1b in retina development.

Methods: An ENU-induced mutation of stxbp1b and a CRISPR-targeted allele of stx3 were used in this study. For rescue experiments, in vitro transcribed mRNA encoding wildtype stxbp1b, phosphomimetic mutant Y474D, non-phosphorylatable mutant Y474F, and wildtype stx3 were injected into 1-2 cell stage embryos. The optokinetic response (OKR) assay was used to screen for visual responses after 5 dpf. Immunolabeling was performed for photoreceptor-specific and synaptic markers. Fluorescence intensity was quantified using ImageJ.

Results: Zebrafish contain two paralogues of STX3, stx3 and stx3a. In situ hybridization of embryos at 48 hours post-fertilization (hpf) shows stx3 expression in the outer nuclear layer of the retina, and stx3a is expressed in the inner retina. Immunolabeling with an antibody to rat Stx3 detected both paralogues with signal on photoreceptors, the outer plexiform layer (OPL) and inner plexiform layer (IPL). In $stx3^{-/-}$ retinas, labeling for Stx3 was largely restricted to the IPL. Quantitative immunolabeling revealed that expression of Stx3 was significantly downregulated in the photoreceptor layer and IPL of stxbp1b mutant retinas. Labeling for other synaptic makers were not altered in the IPL of either mutant retina. All Stxbp1b mRNA injections were enough to rescue photoreceptor morphology. However injected-larvae failed to display an OKR, and the Stx3 immunolabeling of the OPL and IPL remained significantly reduced.

Conclusions: These data indicate that Stxbp1b is essential for Stx3 expression in photoreceptor and Stx3a expression in IPL, suggesting that Stxbp1b acts as a chaperon protein for both Stx3 paralogues. But phosphorylation of Y474 of stxbp1b is dispensable for formation of the outer segment.

ABSTRACT BODY:

Purpose: Recent research has highlighted a significantly high prevalence of visual impairment among Americans with a history of early lifetime substance abuse. The purpose of this study is to further investigate the effects of early lifetime substance use on the eventual onset of severe visual acuity impairment or blindness in this patient population.

Methods: The National Survey on Drug Use and Health was queried to identify all cases of substance use before 21 years of age as well as all cases of significant visual impairment with refraction correction or blindness. Any cases with unknown or arbitrary visual outcomes were eliminated from analysis. Univariable and multivariable binary logistic regression with time-dependency was performed to evaluate odds of visual impairment influenced by 16 individual substances or classes. Adjusted variables of interest included gender, marital status, age bracket, race, level of education, total family income, poverty level, population density, and lifetime history of chronic disease.

Results: After elimination of 312 arbitrary cases, 55824 total cases were considered for analysis with 2577 (4.6%) cases of blindness or significant visual impairment despite refraction correction. Interviewees reporting illicit substance use prior to 21 years of age experienced significantly enhanced odds of eventual vision loss/blindness (OR=1.252, CI 1.175-1.322, $p<0.001$). Specifically, the use of cigarettes, alcohol, marijuana, cocaine, hallucinogens, lysergic acid diethylamide, phencyclidine, ecstasy, inhalants, methamphetamine, and tranquilizers significantly enhanced odds of permanent vision loss. Interviewee-reported substance use yielding borderline/no significance in relation to eventual vision loss/blindness included crack, heroin, pain relievers, stimulants, and sedatives.

Conclusions: Multivariate analysis demonstrated substantially enhanced odds of eventual significant visual impairment with refraction correction or blindness in relation to substance use prior to 21 years of age. A number of commonly abused substances have greater risk for permanent vision impairment. These findings may further help clinicians and public health agencies in mitigation efforts including education, prevention and rehabilitation.

ABSTRACT BODY:

Purpose: Early onset macular drusen (EOMD) is an inherited retinal degeneration where patients develop clinical features similar to AMD early in life. This rare condition is associated with high penetrance genetic variants in the complement factor H (CFH) gene which result in loss of CFH and factor H-like protein 1 (FHL-1) expression. We identified an EOMD family with a novel c.351-2A>G variant in the conserved 3' splice site of exon 4. Induced pluripotent stem cells (iPSC)-derived retinal pigment epithelium (RPE) generated from two EOMD patients heterozygous for the mutation showed significantly reduced (~ 50%) CFH and FHL-1 expression, consistent with haploinsufficiency. This study will examine the effects of CFH/FHL-1 haploinsufficiency on complement inhibition and regulators of complement activators (RCA) in RPE.

Methods: iPSC-RPE derived from healthy controls and EOMD subjects were seeded on Matrigel coated dishes and transwell filters. Media CFH/FHL-1 levels were quantified by WB and ELISA, and an in situ C3b breakdown was performed to assay CFH/FHL-1 function. Expression of soluble complement components were evaluated via real-time PCR and WB. Expression of RCA members were also assessed with real-time PCR and immunostaining. RPE cultured on chamber slides were treated with 10% NHS and stained for C5b-9 to visualize MAC deposition.

Results: EOMD RPE cells had a significantly decreased CFH protein secretion per cell and reduced in situ C3b cleavage activity. In naïve conditions, EOMD RPE had elevated levels of soluble C3bα, C3bβ, and C3bα fragments, consistent with higher C3 turnover. No differences in C5 and CFI protein expression was found. Transcript levels of CD46 (membrane cofactor protein; MCP), CD55 (decay accelerating factor; DAF) and clusterin (CLU) were unchanged, while CD59 and vitronectin (VTN) were significantly increased. On immunostaining, VTN and CLU-positive deposits were found only in EOMD RPE and increased basal localization of CD55 was observed. In response to treatment with 10% NHS, MAC deposition was significantly increased in EOMD RPE compared to controls.

Conclusions: These findings indicate that reduction in CFH and FHL-1 expression contributes to complement dysregulation, suggesting that the RPE cells derived from EOMD patients could be more susceptible to complement-mediated stress.

ABSTRACT BODY:

Purpose:

To evaluate the effect of pupil decentration and visual performance of an active artificial iris smart contact lens design using realistic eye models of keratoconus.

Methods: The artificial iris is based on guest–host liquid crystal cells (GH-LCD) in order to actively modify the transmittance of the lens and effective pupil size. Experimental validation of the GH-LCD spectrum and iris contrast (determined to be 1:2.1) enabled the development of patient-specific eye models for virtual ray tracing analysis in ZEMAX (Focus Software, Tucson, Arizona, USA). A custom methodology was developed to find the optimum pupil centration of the smart contact lens with dynamic artificial iris (6-mm, 4-mm and 2-mm pupil diameters) that produce best optical quality. The optical quality was calculated from simulated wave aberrations in terms of Visual Strehl Ratio (VSR), for 6-mm pupils, and estimated for decentrations ranging from -2 to +2 mm in 0.1 mm steps in horizontal and vertical meridians, referred to the pupil center. The methodology was applied to four keratoconic corneas.

Results: Customized pupil centration resulted in improvements in the image quality when compared with centered pupil positions for all the analyzed cases. On average, optimized pupil position produced a range of 12% to 35% increase in the Visual Strehl, with greater benefit for corneas with higher magnitude of high-order aberrations; i.e., eyes with low visual quality have most to gain with an optimized pupil centration. The visual modelling also suggests an extra increase in the maximum depth-of-focus value for a 4-mm (0.25 D) and 2-mm (0.75 D) pupil diameter for the estimated optimal pupil centration.

Conclusions: Numerical simulations show that the active control of pupil size and centration enhanced the visual function in keratoconus, especially in highly aberrated eyes. This correction could be implemented in practice using customized smart contact lenses with GH-LCD.

ABSTRACT BODY:

Purpose: In individuals with strabismus, fixation preference when making a saccade to an eccentric visual target is thought to be driven by regional visual suppression of the peripheral retina. Here, we compare spatial patterns of fixation preference during visual and memory-guided saccades to understand the potential temporal persistence of visual suppression following the disappearance of a visual target.

Methods: Eye movements were recorded in one exotropic monkey (~25°) while performing visual and memory saccade tasks during binocular viewing. Stimuli consisted of eccentric visual targets presented at random locations within ±30 deg horizontally and ±10 deg vertically. During the memory paradigm, the animal fixated centrally while an eccentric target was flashed for 200ms. Following a variable delay period of 200, 400 or 800ms during which the animal continued to maintain central fixation, the central target was extinguished and the animal made a saccade to the remembered location of the target in darkness. The frequency of an eye acquiring the target at a particular location was calculated to develop fixation preference maps that were then compared between visually-guided and memory-guided saccades.

Results: Alternating and non-alternating saccadic eye movements were detected during both visual and memory paradigms indicating that fixation preference was a property of strabismus irrespective of the continued presence of visual information. Spatial patterns of fixation preference, where targets in the far right visual field were acquired by the right eye and targets in the far left visual field were acquired by the left eye, were observed for both visual and memory-guided saccades. Irrespective of which eye fixated centrally, the border for fixation switch occurred between the lines of fixation (~7°) and was influenced by visual suppression. The area between left and right fixation zones was similar for memory-guided saccades at all delay periods (200, 400 and 800ms) as compared to visually-guided saccades.

Conclusions: Visual suppression in individuals with strabismus influences eye choice behavior for both visually-guided and memory-guided saccades. Temporal dynamics of visual suppression deduced via patterns of fixation preference during memory-guided saccades suggest that effects of visual suppression persists even upto 800ms after the disappearance of visual information.

ABSTRACT BODY:

Purpose: Myeloid cell activation has been implicated in glaucoma pathogenesis in humans and animal models. The purpose of the study is to delineate early myeloid cell activation in an inherited feline model of glaucoma.

Methods: Retinal, optic nerve head (ONH) and distal optic nerve (ON) tissues from 8 juvenile 10-12 week-old cats (4 males and 4 females) with feline congenital glaucoma (FCG) and 5 age-matched normal control cats (3 males and 2 females) were used. Data for weekly intraocular pressure (IOP) and optic nerve axon counts were available for all subjects. Protein and gene expression in tissue cryosections were examined by immunofluorescence labeling (IF) and RNAscope in situ hybridization (ISH), respectively. Retinal tissue was IF labeled for myeloid cell marker, IBA-1 and flat-mounted. ISH for markers of infiltrating monocytes/macrophages (CCR2) and proinflammatory cytokines (IL1A, C1QA, TNF) was performed. Microglia were identified by IF of homeostatic microglial marker, P2RY12. Microscopy images wereanalyzed using Image J, QuPath and Imaris. Two-tailed unpaired t-test or Mann-Whitney test or ANOVA were used for between-group comparisons ($p<0.05$ considered significant).

Results: Mean IOP [SEM] was higher in FCG (19.4 mmHg [3.1]) than age-matched controls (13.5 mmHg [1.8]) ($p<0.001$). Profound microgliosis was observed in the retina and ONH in juvenile FCG cats (no detectable axon damage) compared to age-matched controls ($p<0.01$) whereas ON myeloid cell density was not significantly different between groups. The density of $CCR2^{+}$ infiltrating monocytes was increased in ONHs in FCG relative to controls. While C1QAwas ubiquitously expressed in myeloid cells, only small subsets expressed IL1A or TNF in FCG. The majority of IBA1+ myeloid cells in the retina, ON and prelaminar ONH are positive for P2RY12 in cats, but loss of P2RY12 expression was identified in the retrolaminar region of the ONH in FCG. Myeloid cells in the FCG retina were more morphologically heterogeneous than normal, ranging from ameboid to hypertrophic, with reduced complexity of myeloid cell processes.

Conclusions: Activation of myeloid cells in early-stage FCG is characterized by a subset of proinflammatory myeloid cells, infiltrating monocytes and morphological remodeling in the retina and ONH.

ABSTRACT BODY:

Purpose: Elevated HTRA1 is significantly associated with retinopathy of prematurity (ROP) in human disease and animal models. Mechanisms for this association are not clear. We hypothesize that HTRA1 modulates ocular inflammatory gene expression during hypoxia.

Methods: HtrA1 and inflammatory factors with predicted roles in ROP disease were measured using RT-PCR in murine retinal or retinal pigment epithelial (RPE) cells. ΔΔCt values were compared among P14 transgenic HtrA1 overexpression ($HtrA1^{TG}$) pups and wildtype (WT) C57Bl6J littermate controls under normoxic or hypoxic oxygen induced retinopathy (OIR) conditions (N=3/group). Following humane euthanasia and enucleation, retinal tissue was isolated using microdissection. RPE cells were isolated from choroid via mechanical dissociation in RNAprotect solution for RNA extraction. HtrA1, IL-1ß, TNFα, IL6, and Iba1 cDNA was amplified in triplicate, and Ct values normalized to ß2M. Statistical significance was assessed using one-way ANOVA followed by Bonferroni-corrected two tailed t-tests for multiple comparisons.

Results: Baseline HtrA1 expression in normoxia-reared $HtrA1^{TG}$ pups was 3.3-fold and 19-fold higher in retinal and RPE tissues, respectively ($p<0.0001$) compared with WT littermates. Under OIR conditions, WT retinal HtrA1 levels decreased significantly (2-fold; $p<0.001$), whereas RPE levels did not change. In contrast, OIR conditions in $HtrA1^{TG}$ pups increased HtrA1 expression significantly in both retina (1.5-fold; $p<0.005$) and RPE (2-fold; $p=0.005$). Compared to normoxic conditions, OIR increased $HtrA1^{TG}$ retinal expression of IL-1ß (4.5 fold; $p<0.001$), TNFα (23 fold; $p<0.0001$), and IL6 (4.3-fold; $p<0.005$). In WT retinas, a more moderate hypoxia-induced increase of IL-1ß (3 fold; $p<0.005$) and TNFα (12-fold; $p<0.0001$), but not IL6 were observed. We found no statistically significant expression changes for any inflammatory gene within the RPE.

Conclusions: We demonstrated that inflammatory gene expression was upregulated in hypoxic P14 retinae, further amplified by HtrA1 overexpression. In contrast to previous reports, hypoxia did not increase inflammatory gene expression in RPE cells. However, our study isolated RPE cells from the underlying choroid to prevent contamination from macrophages/monocytes within the choroidal vasculature. Our data suggest that HtrA1-mediated inflammatory activity specific to the retina rather than the RPE can exacerbate ROP.

TITLE: Reliability of Redness Imaging with the Ora EyeCup Phone

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Sinyak, E. bensinger, M. Marquis, J.D. Rodriguez, M.B. Abelson, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Igor Sinyak: Commercial Relationship(s);Code E (Employment):Ora Inc | Ethan bensinger: Commercial Relationship(s);Code E (Employment):Ora Inc | Maurice Marquis: Commercial Relationship(s);Code E (Employment):Ora Inc | John Rodriguez: Commercial Relationship(s);Code E (Employment):Ora Inc | Mark Abelson: Commercial Relationship(s);Code E (Employment):Ora Inc;Code I (Personal Financial Interest):Ora Inc

ABSTRACT BODY:

Purpose: Object measures of symptoms of dry eye are difficult to measure without an expert evaluating the eye in a slit lamp real time. In this study we assess the ability for the Ora EyeCup Phone to consistently capture eye redness in a large patient population. To obtain variations in eye redness patients were exposed to Ora's Controlled Adverse Environment (CAE) with images acquired in the CAE.

Methods: A custom android application on the pixel 5 was used to capture nasal and temporal images from 600 subjects with dry eye disease. Images were captured 29 times during the study, each time collecting a nasal and temporal view of each eye. Images were automatically uploaded from the phones and automatically downloaded onto expert graders computers. Using a custom grading software, graders evaluated each eye with the images with the nasal and temporal images on the screen. If the image was too blurry, the eye was closed or did not reach a sufficient interpalpebral fissure height, or patients gaze was off from the target that eye at that timepoint was marked as ungradable. Some timepoints images did not make it to the grading program either from issues in the upload or image acquisition issues at that timepoint.

Results: Grading of the images is currently still ongoing, but to date total of 133,396 images, or 66,698 sets of nasal and temporal images, have been evaluated by an expert grader. Of these sets only 970 or 1.45% were marked as ungradable. However, some images that were supposed to be acquired and graded did not make it to the graders for reasons listed above. This accounted for an additional 764 missing image sets or 1.15%.

Conclusions: The very low percentage of ungradable sets of images indicates the Ora EyeCup phone provides consistent quality for measuring ocular redness during clinical trials.

ABSTRACT BODY:

Purpose: Diabetes predisposes an individual to severe COVID-19. Diabetic cornea is also known to have impaired wound healing, increasing the chances of infection. Earlier, we reported the ability of SARS-CoV-2 to infect conjunctival cells, and the presence of viral RNA and proteins was also detected in the corneas of COVID-19 donors. In this study, we evaluated the effect of diabetes on corneal innate immune response during SARS-CoV-2 infection and sought to determine the underlying mechanisms.

Methods: Human primary corneolimbal epithelial cells (HCECs) were isolated from the corneas of three diabetic and three non-diabetic donors. In vitro studies were performed by infecting HCECs with SARS-CoV-2 – USA-WA1/2020 strain at MOI 0.5. Viral replication was assessed by viral genome copy number. RNAseq analysis was performed to determine genes/pathways altered by diabetic vs non-diabetic HCECs. qPCR was used to assess the expression of innate inflammatory and antiviral genes. Western blot was performed to detect the protein expression of antiviral signaling molecules.

Results: The primary HCECs were found permissive to SARS-CoV-2 infection, as evidenced by increased viral replication which peaked at day 3 p.i. along with an induction of p-STAT1. Interestingly, HCECs from diabetic cornea had higher viral RNA on all three days post-infection. SARS-CoV-2 infected HCECs exhibited induced expression of inflammatory genes and their levels were relatively higher in diabetic cells. RNA-seq analysis revealed significant differences in diabetic vs. non-diabetic SARS-CoV-2 infected cells with alteration in genes regulating viral response, inflammation, and injury. The most affected down-regulated genes are related to lipid metabolism, ferroptosis, and oxidative stress.

Conclusions: Our study demonstrates increased SARS-CoV-2 replication and differential innate antiviral and inflammatory response in HCECs from diabetic corneas. These results indicate that diabetes is a potential risk for enhanced infectivity of SARS-CoV-2 for the ocular surface.

ABSTRACT BODY:

Purpose: Deep learning (DL) can assist the diagnosis of diabetic retinopathy (DR) based on optical coherence tomography angiography. However, it is unclear how deep learning classification models arrive at their results, limiting discovery of DR biomarkers. To improve interpretability, a novel biomarker activation map (BAM) generation framework based on generative adversarial learning (GAL) is proposed.

Methods: 50 healthy participants and 305 patients with diabetes were recruited in this study. Masked trained retina specialists graded each eye based on 7-field fundus photography using early treatment of diabetic retinopathy study (ETDRS) criteria as either non-referable (nrDR; ETDRS score < 35) or referable (rDR; ETDRS score ≥ 35 or macular edema). Macular 3×3-mm scans for one or both eyes of each participant were acquired using a commercial 70-kHz spectral-domain OCT system. 456 superficial vascular complex (SVC) en face OCTA images were collected. The data set was divided into training (60%), validation (20%), and testing (20%) sets and used to train a referable/non-referable DR classifier that used the en face SVC angiograms as input. Two U-shaped networks were also trained as generators. The main generator was trained to produce an angiogram that the classifier would classify as nrDR from an input angiogram, while the assistant generator produces angiograms that would be classified as rDR (Fig. 1). The BAM was finally constructed as the absolute difference image between the input angiogram and output of the main generator.

Results: The diagnosis of rDR achieved an overall accuracy of 92%. Compared to the traditional class activation maps (CAMs) (Fig. 2B), the generated BAMs explicitly highlighted most of the pathological nonperfusion area, which represents the most important DR biomarker visible in the input angiogram (Fig. 2E). Unlike traditional CAMs, the BAMs ignored non-pathological features like the foveal avascular zone while emphasizing real pathological features that contribute the diagnostic decision making.

Conclusions: The generated BAMs using GAL method could provide sufficient interpretability to help clinicians utilize DL-aided referable DR screening, and help to quickly discern the DR-related pathologies. This innovation may also facilitate the new biomarker discovery on OCTA used for diagnosis of retinal vascular diseases.

ABSTRACT BODY:

Purpose: Photoreceptors (PRs) have prodigious energy and biosynthetic demands. Most of the glucose delivered to PRs is converted to lactate, instead of pyruvate, via aerobic glycolysis. Due to this limited pyruvate, PRs need to utilize alternative fuels to supply tricarboxylic acid (TCA) cycle metabolites and support energy production and biomass. Glutamine (Gln) contributes to biosynthesis, energetics, and redox balance in other bioenergetically demanding cells. This study assessed the contribution of Gln catabolism to PR metabolism, function, and survival.

Methods: To study the role of Gln catabolism in vivo in PRs, we generated a rod PR-specific glutaminase (Gls) conditional knockout ($Gls^{fl/fl}$: Rho-Cre; Gls cKO) and a rod PR-specific tamoxifen inducible Gls conditional knockout ($Gls^{fl/fl}$:Pde6g-Cre^{ERT2}). Immunohistochemistry (IHC) and western blot analysis addressed the abundance and location of GLS. The function and survival of PRs was examined using OCT, ERG, and histology. Targeted metabolomics assessed the metabolic state in cKO and control retinas. RT-PCR analyzed the expression of genes involved in glutaminolysis, redox balance, and cell death.

Results: Rod PR-specific knockdown of GLS (Gls cKO) was validated with IHC and western blot, and metabolomics confirmed the substrate of GLS, Gln, was increased, and its product, glutamate, reduced. Gls cKO retinal metabolomics at P14 demonstrated decreased pyruvate, lactate, and aspartate. Correspondingly, the expression of genes involved in pyruvate metabolism, Pdha/b and Pcx, were increased while Pdk was decreased. The expression of transaminase Bcat1 and TCA cycle genes were also increased. Oxidative defense genes, Sod1/2, were upregulated as were markers of apoptosis, necroptosis, and ferroptosis. These molecular changes resulted in the Gls cKO mouse demonstrating comparable outer nuclear layer (ONL) thickness to controls at P14 with rapid and complete PR degeneration thereafter. Increased TUNEL staining in the ONL and GFAP staining was noted at P21. In accordance with these anatomic findings, Gls cKO mice showed significant decreases in scotopic amplitudes via ERG. Inducing knockdown of GLS in mature rod PRs with tamoxifen at P45 also resulted in significant degeneration.

Conclusions: This study demonstrates that GLS-mediated Gln catabolism is essential for PR metabolism, function, and survival.

ABSTRACT BODY:

Purpose: Two-photon vision is the perception of short-pulsed near-infrared laser radiation (800-1200 nm) focused on the retina as having color as 400-600 nm, their half-wavelength counterparts. It is due to a nonlinear optical phenomenon - the two-photon absorption occurring in visual pigments (PNAS 111(50), E5445, 2014). To date, the effect of different beam sizes on the cornea on the two-photon thresholds has not been investigated. The present work provides experimental data to address this issue.

Methods: The two-photon (1040 nm, laser pulse duration 200 fs and repetition frequency 76 MHz) and one-photon (520 nm) visual thresholds of 4 dark-adapted healthy volunteers (2 women, 2 men, 32-43 y.o.) were determined by using 4-2-1 staircase strategy with a custom-build optical system. The stimulus was a circumference of 0.5 deg diameter, centered at fovea, obtained by fast scanning the retina with laser beams. The measurements were performed for 3 diameters of stimulating beam at cornea: 0.36 mm, 0.6 mm, and 1.2 mm for each wavelength. For each diameter, 5-7 various degree of defocus was applied around the best correction position found subjectively by each volunteer. The pupils of subjects were dilated, and accommodation was blocked by using 1% Tropicamide. The study was approved by the Ethics Committee of the Collegium Medicum, NCU.

Results: The mean two-photon thresholds calculated for all participants lie on 3 parabolas corresponding to the beam diameters at the cornea, each with a minimum located near (less than 0.3 D) the position of best correction. The parabolas became tighter and the mean threshold value (±1SD) at minimum decreases with increasing the size of the beam on the cornea: 18.1±3.4 μW, 9.8±1.6 μW, and 5.1±1.4 μW for 0.36 mm, 0.6 mm, and 1.2 mm diameter, respectively.

For one-photon stimulus, the discrepancies between individuals were greater and a significant difference between visual thresholds was observed only for 0.36 mm and 0.6 mm beam: the mean minimal visual thresholds were equal to 36±15 fW and 21±6 fW, respectively. The thresholds for the 1.2 mm diameter beam were roughly similar to the minimum found for 0.6 beam: 20±12 fW.

Conclusions: The data show that the size of the beam on the cornea significantly affects the two-photon visual threshold. The lack of difference between the 1.2 mm and 0.6 mm beams for single-photon (520 nm) vision may be due to more significant aberrations in the eye for this wavelength.

TITLE: Deficiency of the transcription elongation factor Ell2, a downstream target of the cataract-linked RNA-binding protein Celf1, causes eye defects

SESSION TITLE: Lens Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Shrestha, S. Aryal, A. Siddam, F. Hernandez, S.A. Lachke, Department of Biological Sciences, University of Delaware, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure: Sanjaya Shrestha: Commercial Relationship: Code N (No Commercial Relationship) | Sandeep Aryal: Commercial Relationship: Code N (No Commercial Relationship) | Archana Siddam: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Salil Lachke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently showed that the cataract-associated RNA-binding protein (RBP) Celf1 post-transcriptionally controls the key transcription factors Pax6 and Prox1 in the lens. To further understand the regulatory relationship between RBPs and the factors that control transcription in the lens, we focused on Ell2 (Elongation factor for RNA Polymerase II 2), which we found to be abnormally over-expressed in the lens in Celf1 lens-specific conditional knockout ($Celf1^{cKO}$) mice and which was independently identified by iSyTE as a high-priority candidate gene in the lens.

Methods: Ell2 expression in lens development was evaluated by RT-PCR, in situ hybridization (ISH), Western blotting (WB) and immunostaining (IF). Germline ($Ell2^{-/-}$) and lens-specific conditional KO mice ($Ell2^{cKO}$) were generated by crossing mice carrying Ell2 floxed alleles with CMVCre and Pax6GFPCre mouse lines, respectively.

Results: Ell2 overexpression in $Celf1^{cKO}$ mouse lens as suggested by microarrays and RNA-sequencing was independently validated by RT-qPCR. Further, RNA-immunoprecipitation (RIP) using Celf1 antibody indicated that Celf1 protein directly binds Ell2 RNA in lens cells. These data, along with iSyTE-based lens-enriched expression analysis, identified Ell2 to be a high-priority target in the lens. RT-PCR confirmed robust Ell2 RNA expression in mouse lens at various stages and ISH showed that Ell2 RNA is present in fiber cells near the transition zone at E16.5. WB confirmed Ell2 protein (~72 kDa) in mouse lens and immunostaining showed Ell2 protein levels in lens fiber cell nuclei at embryonic and postnatal stages. In agreement with Ell2's robust expression in the lens, $Ell2^{-/-}$ and $Ell2^{cKO}$ mice showed ocular defects, including small eye and lens abnormalities.

Conclusions: Ell2 has been shown to interact with RNA polymerase II and increase its elongation rate along template DNA by relieving the transient "pause" in the early stages of transcription. While Ell2 has been associated with cancer and other defects, its role in eye development has not been examined. This study identifies Ell2 as a novel downstream target of the cataract-linked gene Celf1 and validates its robust expression at the RNA and protein levels in the lens. Further, $Ell2^{-/-}$ and $Ell2^{cKO}$ mice exhibit ocular defects indicating its important role in the eye and lens.

ABSTRACT BODY:

Purpose: Inhibition of macrophage migration inhibitory factor (MIF) has shown promise protecting retinal neurons in excitotoxic retinal damage models. We evaluated the ability of three MIF inhibitors (MIFi) to improve electroretinography (ERG) function in the chick excitotoxic retinal damage model.

Methods: Experiments were performed under an IACUC approved protocol. White leghorn chicks (n=3/group) were given intravitreal injections with NMDA (500nmol) at day 0 (D0) plus one of three different MIFi: ibudilast, AV1013, or CPSI-1306 at 1.0 mg/ml or vehicle (sterile water). Injections of MIFi and vehicle was performed on D-1, and D0. ERG waveforms were captured between D10-D14 with the Celeris ERG system. Light adapted ERGs and oscillatory potentials were captured with flash intensities between 0.05 and 25 cd*s/m^2. Additionally, 20Hz flicker and long flash ERGs were recorded. Statistics were calculated in Graphpad PRISM using ANOVA with Tukey and Dunnett multiple comparison testing. A p-value ≤ 0.05 was considered statistically significant.

Results: ERG measurements resulted in no significant differences between MIFi-treated and vehicle-treated NMDA-damaged eyes in the CPSI-1306 and AV1013 groups. Ibudilast treatment resulted in significant improvement in two groups: the ERG b-wave and the long flash ERG bipolar-ON wave. NMDA-damaged eyes treated with ibudilast were found to have significantly higher b-wave amplitudes at 3, 8, and 13 cd*s/m^2 (177.24±47.04 μV vs 278.60±61.78 μV, p=0.0049; 192.08±64.39 μV vs 279.90±40.62 μV, p=0.0173; 183.16±66.67 μV vs 265.00±27.23 μV, p=0.0288; NMDA+vehicle vs NMDA+ibudilast, respectively). The ON waves were also improved due to statistically higher amplitudes (11.09±5.26 μV vs 35.54±22.68 μV, p=0.0170; NMDA+vehicle vs NMDA+ibudlast). Both of these waveform groups correspond to inner retinal neurons, which are most susceptible to excitotoxic damage caused by NMDA.

Conclusions: Ibudilast is approved in Japan for neurologic and inflammatory indications and is in clinical trials for multiple sclerosis in the US. Preliminary results show ibudilast is promising for excitotoxic retinal damage prevalent in many retinal disorders like blast injury, diabetic retinopathy, vein occlusion and retinal ischemia.

ABSTRACT BODY:

Purpose: To report the wide-field choroidal vascularity up to the mid-equator area in diabetic retinopathy (DR) subjects using wide-field optical coherence tomography (WF-OCT).

Methods: This is an observational, cross-sectional study. WF-OCT images (55 degrees) were obtained using Spectralis HRA+OCT (Heidelberg Engineering, Germany) in extremes of gazes in all quadrants and manual montages were created to obtain wide field images up to mid equator. A previously reported semi-automated algorithm was used to calculate choroidal vascularity profile (CVI). Regression analysis was performed to identify the factors influencing CVI.

Results: Forty-seven eyes from 25 patients were enrolled in the study. The mean age was 68.4±10.6 years. The refractive error (spherical equivalent) ranged from -2.25 to +3.75 diopters. Most common DR grade among study subjects was moderate NPDR (29.41%) and 74.5% eyes had diabetic macular edema (DME). The mean CVI in the macular area (58.29±3.63) was significantly lower than in any of the other fundus areas (all $p \leq 0.01$). The maximum CVI was seen in the nasal region (66.60 ± 5.61), followed by temporal (65.69 ± 3.81), superior (65.01 ± 4.87), and inferior (63.80 ± 5.42). The vertical macular area had the least coefficient of variation (CV) of CVI (0.06) while the inferior quadrant had the highest CV (0.08).

Conclusions: The current study describes the CVI profile on WF-OCT in DR eyes upto mid-equator. The significant increase of the CVI compared to healthy subjects and its significant regional variations introduce this novel quantitative parameter as a reliable biomarker of the diabetes-induced choroidal microangiopathy.

ABSTRACT BODY:

Purpose: To evaluate whether ultrawide field integrated SS-OCT can be used to distinguish between nonproliferative features such as intraretinal microvascular abnormalities(IRMA) from proliferative features such new vessels(NV).

Methods: This cross-sectional study evaluated patients with severe nonproliferative diabetic retinopathy (NPDR)who presented to a single MD retina clinic (MA) at the Beetham Eye Institute from July 1 to Dec 15, 2021.Patients were imaged on a device combining UWF color imaging(CI) and navigated SS-OCT (Silverstone,Optos). A 12-mm raster protocol (macula, optic nerve head and superotemporal to inferotemporal arcades) and mid-peripheral volume scans in all four quadrants were performed. Any area with suspected NV or large IRMA (>8A) were imaged. A clinical assessment and UWF stereoscopic CI grading by the MD providing clinical care was performed. Lesions were considered to be NV if they were seen to break through the internal limiting membrane on SS-OCT.

Results: The study included 14 eyes of 8 patients with diabetes mellitus. 25.0 % were female, mean age of 51.5±7.97 years,42.9% had type 1 DM, with a mean duration of 23.4±9.3 years, and an average A1c of 8.4±1.9%. A total of 24 IRMAs were suspicious for NVE on UWF-CI grading. 21 (87.5%) were captured on navigated OCT with 3(12.5%) located outside the imaged area. Among IRMA imaged(N=21), evaluation of SS-OCT image determined that 5 lesions(23.8 %) were NVE and not IRMA. Of these, 3 were flat and confined to the posterior hyaloid face and 3 had forward extension and vitreous invasion. In one eye an additional NVE was detected that was not previously flagged as a suspicious NVE. The NVE identified resulted in a change in the DR grading from severe NPDR to PDR in 4 eyes(21.4%).

Conclusions: This pilot study explores the possible clinical utility of navigated SS-OCT in assessment of IRMA in subjects with severe NPDR. Initial findings suggest a substantial portion of eyes may have undetected proliferative disease that can be identified using this modality and thus further investigation is warranted. Future studies will include a larger cohort of patients to compare between OCT/UWF-CI grading, UWF-CI grading alone and UWF-FA to establish whether this approach provides benefit to existing imaging modalities with regard to IRMA as well as all other important diabetic retinopathy lesions.

TITLE: Functional diversity of intrinsically photosensitive retinal ganglion cells in the mouse retina.

SESSION TITLE: Retinal ganglion cells and central processing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Sivyer, M. Berry, Ophthalmology, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Benjamin Sivyer: Commercial Relationship: Code N (No Commercial Relationship) | Michael Berry: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There are six main ‘types’ of melanopsin expressing intrinsically photosensitive retinal ganglion cells (ipRGCs) in the rodent retina (M1-M6). Recent studies indicate there is likely an increased diversity within these groups but this functional diversity remains uncertain. We have recently identified a subtype of M1 ipRGCs coding for reflected luminance which forms the primary projection to the supraoptic nucleus (SON) of the hypothalamus. These results illustrate at least two distinct anatomical subtypes of M1s in the dorsal retina. Our hypothesis for the present study is that M1 ipRGCs comprise multiple functional subtypes in the dorsal retina.

Methods: To test this hypothesis, we combined multielectrode array (MEA) recordings (256 channels) with optogenetics to ‘Opto-tag’ channelrhodopsin-expressing ipRGCs. The dorsal retina of dark-adapted GlyT2Cre::Ai32 mice (n = 4 retinas from 3 mice) was dissected and maintained in a recording chamber at 32 C. Light responses to scotopic, mesopic, and photopic (=visual stimuli included luminance steps, chirp stimuli, UV/green color stimuli, and 1 minute long steps. Spike data was sorted and ipRGCs were functionally classified using unbiased clustering methods.

Results: We found 8 functional clusters of ipRGCs (n = 282 ipRGCs) that differed in their sensitivity, response latency, and maintained spiking. Two of the most sensitive functional clusters (clusters 3 and 5) had profoundly different light responses. Cluster 3 had transient responses to illumination (response duration 15.92 ± SEM 3.1s; n = 18 ipRGCs p <0.0001) and apparent depolarization block to sustained visual stimuli and/or high light intensities. This group fired only transiently to a 60-second visual stimulus (response duration 1.47 ± SEM 0.15; n = 18 p< 0.0001). Cluster 5 had sustained responses to all light intensities (response duration 75.39 ± 1.5s; n = 32 ipRGCs; p<0.0001) and was able to spike continuously during the 60s stimuli. The majority of the Opto-tagged cells fell into cluster 5 (n = 17 of 32) while none were found in cluster 3 (n = 0 of 18).

Conclusions: The mouse retina has 8 functional clusters of ipRGCs and the two most sensitive (presumptive M1 ipRGCs) fall into two distinct functional groups. Our data suggest that a unique population of M1 ipRGCs projecting the SON of the hypothalamus encodes sustained luminance information.

ABSTRACT BODY:

Purpose: Oxygen plays a central role in multiple physiological and pathophysiological processes, and retinal oxygen supply has been found to be an important factor in many ocular diseases. Zilia has developed an oximetry technology that allows oxygen saturation (StO2) measurements in targeted locations of the retinal tissue. The objectives of the study were to evaluate the stability of StO2 measurements over the period of acquisition, the repeatability of measurements at a given location, establish preliminary normative data, compare oximetry levels in individuals in different regions of the eye fundus.

Methods: 24 subjects (16 females, 8 males, age ranging from 19 to 83) were enrolled for this study. Acquisitions consisted of 10-sec measurements in 3 locations of the eye fundus: inferotemporal optic nerve head (ONH), macula and nasal retina. Four subjects were randomly selected for repeated measurements at the same locations in the same eye after 15-30-min breaks.

The minimum period of acquisition required to obtain reliable StO2 measurements was established. Paired T-tests were performed to assess repeatability and compare StO2 variations in the different regions of the fundus.

Results: No significant difference was observed between 2 successive measurements at the same location (separated by 15-30 min breaks). Mean StO2 was 67.3%±5.57% in the ONH, 62.1%±4.69% in the nasal retina and 43.63%±10.97% in the macula. Significant differences in StO2 measurements were observed between the ONH tissue and the nasal retina ($p<0.025$), the ONH and the macula ($p<0.0001$), and the nasal retina and the macula ($p<0.0001$)

Conclusions: Ocular oximetry offers a unique window into the retina and systemic health by means of examining hemodynamics. Until now, retinal oximeters have offered semi-quantitative information about the oxygenation in large superficial retinal blood vessels. However, to become useful in clinical settings, a technology enabling reproducible quantitative oxygenation measurements, both in the superficial blood vessels and the underlying capillaries present in the intervessel tissues, is desirable. The present study demonstrates the efficacy and reproducibility of the Zilia ocular oximetry technology towards measuring StO2 of the microcapillary network within the retina and the ONH.

ABSTRACT BODY:

Purpose: Radiation retinopathy (RR) commonly causes poor, long-term visual acuity outcomes in patients previously treated with radiation plaque, proton beam, or orbital radiation therapy. Current treatments are not FDA-approved and prior studies have had variable outcomes with small sample sizes. We performed a multi-center, prospective, randomized clinical trial to assess the safety and efficacy of 2 mg intravitreal aflibercept injections (IAI) given in a treat-and-extend regimen for radiation retinopathy and optic neuropathy.

Methods: Thirty-nine eyes in 39 patients with RR were assigned randomly to cohorts (1:1 ratio) in which patients either did or did not receive a loading dose of 3 IAI followed by a treat-and-extend regimen. The primary outcome measure was the mean Early Treatment Diabetic Retinopathy Study (ETDRS) best-corrected visual acuity (BCVA) change from baseline. Statistical analyses were performed using Student’s t-tests for comparison of groups.

Results: At baseline, mean patient age was 58.18 years (range, 23-81), 53.85% of patients were female, mean ETDRS BCVA was 58 letters (range, 20 - 83), and mean central retinal thickness (CRT) was 472 µm (range, 294 – 927) at baseline. Thirty-six patients completed the Month 12 visit (92.3%). There was a significant difference in the overall mean BCVA change between cohorts, with 2.8 letters and 7.5 letters gained in cohorts 1 and 2, respectively ($p < 0.01$). Additionally, there was a significant difference in CRT from baseline to week 52 overall (472.92 µm to 314.47 µm) and within cohorts 1 (442.6 µm to 295.4 µm) and 2 (504.8 µm to 333.6 µm), respectively ($p < 0.001$). 97.2% of patients had visual acuity of 20/200 or better, and 30.56% improved 10 or more ETDRS letters.

Conclusions: In this cohort of patients, aflibercept improved vision and CRT in patients with radiation retinopathy using a treat-and-extend regimen compared to historical controls.

ABSTRACT BODY:

Purpose: Our lab has generated novel lipid nanoparticles (LNPs) for delivery of gene editors to the retina and demonstrated robust transfection of the rodent retina. The goal of this study was to evaluate retinal transfection efficiency in a more clinically relevant model, the non-human primate (NHP).

Methods: Novel LNP variants were prepared via rapid microfluidic mixing of an organic phase containing the lipids (ionizable lipid, DSPC, sterols, and PEG) and aqueous phase containing GFP mRNA. LNPs were characterized for hydrodynamic radius, polydispersity index (PDI), encapsulation efficiency and zeta potential (ZP). LNPs were transfected into NHP iPSC-derived RPE cells at multiple doses ranging from 500 ng to 10 µg. Rhesus macaques received baseline optical coherence tomography (OCT), fundus autofluorescence (FAF) and ultra-wide-field imaging. Subretinal surgery was performed by a skilled retinal surgeon using an Alcon Constellation vitrectomy machine to deliver 100 µl (50 µg total) of LNPs to each bleb per eye. No systemic immune suppression was used. At 48 hours post-injection, in vivo retinal imaging was performed and eyes were then harvested for histology and immunohistochemistry (IHC). LNPs were also subretinally delivered to WT C57BL6 mice. In vivo retinal imaging and IHC of retinal sections were performed to characterize intracellular gene expression.

Results: All LNPs had a diameter <85 nm, with a PDI <0.10. The ZP of the particles varied from -1.1 to -5.3 and encapsulation efficiency ranged from 98-99%. GFP expression was observed in NHP iPSC-derived RPE cells at 48 hours post-LNP transfection at all doses tested. Baseline imaging confirmed that all macaques had normal retinal morphology prior to surgery. At 48 hours post-injection, in vivo retinal FAF imaging showed robust GFP expression in the subretinal blebs. IHC demonstrated GFP expression localized to photoreceptors, RPE and Müller glia (Figure 1). Evaluation of the same particles in WT mice on the same day confirmed GFP expression and localization.

Conclusions: LNPs successfully transfected many retinal cells in the NHP including photoreceptors, RPE and Müller glia post-subretinal delivery. These data demonstrate the translatability of LNP-mediated gene delivery to retinal cells across species and support their development as delivery systems for retinal disease therapies.

TITLE: The impact of unconjugated hyperbilirubinemia on angiogenic and oxidative stress genes in the neonatal rat retina exposed to LPS.

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Molomjamts, K. Satrom, T. Gisslen, E.C. Ingolfsland, Pediatrics, University of Minnesota Twin Cities, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Mandkhai Molomjamts: Commercial Relationship: Code N (No Commercial Relationship) | Katie Satrom: Commercial Relationship: Code N (No Commercial Relationship) | Tate Gisslen: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Ingolfsland: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) and unconjugated hyperbilirubinemia are common comorbidities found in preterm infants. As a potent antioxidant, low dose unconjugated bilirubin (UCB) may have a protective effect against the development of ROP, particularly in conditions of oxidative stress such as sepsis, yet it has not been tested in a preclinical study. We hypothesize that key oxidant stress factors and endothelial cell angiogenic factors are upregulated in retinas of jaundiced pups when exposed to lipopolysaccharide (LPS).

Methods: The Gunn rat model of neonatal jaundice was used in this study. Homozygous jaundiced pups (jj) and littermate non-jaundiced heterozygous (Jj) controls received intraperitoneal saline or LPS on postnatal day (P)5 and were euthanized on P7. Whole retinal dissection was performed. Retinas from 3-6 pups/group underwent RNA extraction, cDNA synthesis, and quantitative polymerase chain reaction (qPCR) with Vegfa, Ang2, Slit2, Birc5, p53, and GPX4 probes and normalized against PPIA. Outliers were identified by ROUT test (Q=1%) and comparisons were made by two-way ANOVA ($P<0.05$) (GraphPad Prism 8).

Results: LPS upregulated mRNA expression of angiogenic factors, Vegfa by threefold, Ang-2 by threefold, and Birc5, downstream target of Ang-2, by fourfold compared to saline groups at P7 ($p<0.05$). Antioxidant GPX4 and pro-oxidant P53 mRNA expression were upregulated threefold and twofold respectively in LPS groups compared to saline groups. There were no significant differences in any tested genes between Jj and jj groups.

Conclusions: LPS increased gene expression of key angiogenic molecules and had a mixed effect on pro-and anti-oxidant factors in the neonatal rat retina. These effects were not altered by the presence of unconjugated hyperbilirubinemia, despite previous evidence from our group describing the heightened antioxidant effects of unconjugated hyperbilirubinemia in the brain, which may suggest a differential effect from the blood-retina barrier. The induction of angiogenic factors by LPS in the retina validate published findings but further study is needed to determine if increased GPX4 by LPS may ameliorate its pathogenic role in ROP.

ABSTRACT BODY:

Purpose: Despite advances in treatment, diabetic retinal disease (DRD) is a leading cause of vision loss for working-age adults worldwide. The development of novel, more effective therapies to preserve and restore vision is limited by current staging systems for DRD. These do not evaluate the neurosensory or peripheral retina, systemic health or molecular targets, and do not directly address impact of DRD on visual function or quality of life. The goal of this work was to define promising variables for a revised DRD staging system to better define DRD, stage risk of disease worsening and predict treatment response.

Methods: Six working groups conducted narrative reviews in the areas of: vascular retina, neural retina, visual function, quality of life, basic and cellular mechanisms, and systemic health to identify promising biomarkers for DRD risk, disease progression, and treatment response. Targeted reviews of the literature were conducted by a total of 50 experts in DRD from 12 countries, who used standardized evidence grids to collect information about each parameter.

Results: Selected tests and variables of interest included “traditional” ETDRS lesions, predominantly peripheral lesions on ultrawide field imaging, electroretinography, spectral domain optical coherence tomography, hemoglobin A1c, diabetes duration, and multiple molecular pathways. Visual function tests included best corrected visual acuity, contrast sensitivity, low luminance visual acuity and static automated perimetry. Quality of life instruments ranged from paper-pencil questionnaires to the RetCAT computerized adaptive testing system. Key information will be presented in each working group area to define the current level of evidence for promising parameters and to identify major gaps in knowledge that need to be addressed in future clinical and translational studies.

Conclusions: The DRD Staging System Update initiative is the first step in a Restoring Vision Moonshot™ which will expand access to data sharing and collaboration platforms to enable restoration and preservation of visual function in persons with diabetes. The second step is the establishment of a human eye tissue and the third step is development of a curated retinal image bank. The ultimate goal of this “Moonshot” is to create a world without visual loss from diabetes, a mission inspired by the late Mary Tyler Moore.

TITLE: Exploring digital exclusion for patients using remote consultations at Moorfields Eye Hospital.

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Sehmi, S. Kang, D. Sim, R. Mathew, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Amrit Sehmi: Commercial Relationship: Code N (No Commercial Relationship) | Swan Kang: Commercial Relationship: Code N (No Commercial Relationship) | Dawn Sim: Commercial Relationship: Code N (No Commercial Relationship) | Rahsmi Mathew: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The use of video consultations was scaled urgently at Moorfields Eye Hospital due the COVID-19 pandemic, and has been sustained within the Trust. This provision was much needed and initiated without the usual stakeholder engagement. Digital exclusion will drive health inequalities in our patients, unless we fully understand it and create solutions to make our services accessible for all. The aim of the project is to understand the reasons why patients failed to utilise digital services during the pandemic.

Methods: A retrospective analysis of all patient-initiated video consultation cancellations from December 2020 to November 2021 was undertaken. All rebooked appointments were excluded from analysis. Reasons for cancellation were extracted from the Patient Appointment System (PAS) to identify those who were digitally excluded. Patients who had opted out of data sharing or cancelled their video consultation but had attended another subsequent appointment were excluded from the analysis for digital exclusion.

Results: Over a 1-year period, 10,457 video consultations were undertaken at Moorfields Eye Hospital. 5% (535) of appointments were cancelled by patients. Of these, 14% (73 patients) were digitally excluded. Digital exclusion was due to 3 main factors; lack of resources (53%), lack of skills (19%), lack of trust in the video consultation model (19%), or a combination of these factors (9%).

The age range of digitally excluded patients was 9 to 89 years old. Those most digitally excluded were the 70-79 year olds (26%, 19 patients). The least digitally excluded age group were the 20-29 years olds (1%, 1 patient).

In terms of sub-speciality, 52% (38 patients) were from the adnexal service, 27% (20 patients) from general ophthalmology, 12% (9 patients) from paediatric ophthalmology, and the remainder from ocular oncology (4%), strabismus (3%) and medical retina (1%).

Conclusions: The reasons for digital exclusion are complex, but need to be understood and addressed, if we are to continue to scale digital services in the health sector and without widening health inequalities. Our work identified 3 main factors, with lack of resources being the overarching reason. Further implementation research in the fields of digital resource provision coupled with education may enable greater inclusion of this group of patients and enhance digital healthcare provision equality.

TITLE: Activation of the aryl hydrocarbon receptor inhibits IGF1R and TSHR-mediated signaling in thyroid eye disease

SESSION TITLE: Thyroid eye disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Woeller, S.E. Feldon, E. Roztocil, Department of Ophthalmology, University of Rochester Medical Center, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Collynn Woeller: Commercial Relationship: Code N (No Commercial Relationship) | Steven Feldon: Commercial Relationship: Code N (No Commercial Relationship) | Elisa Roztocil: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Thyroid eye disease (TED) is an autoimmune disorder that can lead to proptosis, optic neuropathy and vision loss. In TED, the connective tissue behind the eye becomes inflamed, remodeled and enlarged. Thyroid stimulatory hormone receptor (TSHR) and insulin-like growth factor 1 receptor (IGF1R) signaling are central mediators of TED pathology. Teprotumumab, an IGF1R blocking antibody, recently became the first disease-specific treatment for TED. While teprotumumab represents a major advance and reveals TED specific treatments are feasible, there are limitations with the therapy including: incomplete patient response, patient relapse after therapy, undesirable side effects and cost. Therefore, additional therapies are needed. The objective of this research was to investigate the ability of the aryl hydrocarbon receptor (AHR) to block IGF1R and TSHR signaling in TED orbital fibroblasts.

Methods: Primary human orbital fibroblasts from TED patients and non-TED patients and HEK293FT cells were cultured under standard conditions. HEK293FT cells were transfected with TSHR cDNA and a cyclic-AMP response element (CRE) dependent luciferase reporter construct. Orbital fibroblasts or reporter cells were treated with IGF1, TSH or TED patient specific antibodies in the presence or absence of the AHR activating compounds, FICZ or esomeprazole (a proton pump inhibitor). Cells were collected and analyzed using luciferase reporter assays and quantification of phosphorylation of downstream cell signaling proteins (AKT and CREB). Cell migration was measured using scratch assays in cells treated with or without IGF1.

Results: Activation of TSHR by TSH or TED patient antibodies led to a robust increase in CREB phosphorylation and CREB-dependent luciferase activity in TSHR-expressing reporter cells. Activation of the AHR by FICZ or esomeprazole inhibited TSHR-induced CREB signaling. In TED orbital fibroblasts, IGF1R signaling induced phosphorylation of AKT and increased cell migration. Esomeprazole and FICZ mitigated IGF1-induced AKT phosphorylation and fibroblast migration in a dose-dependent manner.

Conclusions: These data show that activation of the AHR by FICZ or esomeprazole inhibit TSHR and IGF1R signaling. Given that both IGF1R and TSHR pathways are key mediators of TED pathology, these studies reveal that AHR activation may be a novel mechanism to treat TED.

ABSTRACT BODY:

Purpose: An external validation of an automated Artificial Intelligence AI- and color fundus image-based model for detection of disc hemorrhage, a significant risk factor in glaucoma progression.

Methods: A deep machine learning architecture named “EfficientNet B5”, pre-trained with the “ImageNet” dataset, was implemented to train a network to detect the disc hemorrhages in fundus images. For this, 150 images with disc hemorrhages and 650 normal or without disc hemorrhages were used to train and test the model. Full-color fundus images were first cropped using automated AI to get only the optic disc area of the retina. These images were then resized to 100x100 pixels. This helps in reducing the number of retinal features that the network encounters, given the relatively small size of training data. The image sets were randomly augmented at each epoch for variation with rotation, translation and sheering with noise addition that resulted in newly generated images upto 35 times the original number. An early stopping mechanism was employed wherein the training is stopped if no improvement in training loss is seen in 25 consecutive epochs. The network weights with the best training loss were saved. For external validation, we have used another dataset obtained from the Department of Ophthalmology at Icahn School of Medicine at Mount Sinai. This dataset consisted of 144 images with disc hemorrhage and 831 normal or without disc hemorrhages.

Results: For detection of disc hemorrhage on the external validation dataset, we achieved 93.13% accuracy (95% CI: 91.35% to 94.64%) with a sensitivity of 71.53% (95% CI: 63.42% to 78.73%), a specificity of 96.87% (95% CI: 95.45% to 97.95%) and a kappa score of 0.71 (95% CI: 0.65 to 0.78).

Conclusions: We have performed an external validation study of the automated disc hemorrhage detection from a color fundus image. In the future, we aim to improve the sensitivity by adding more data and study the tool prospectively with deployment in clinical settings.

ABSTRACT BODY:

Purpose: NADPH oxidase 4 (Nox4) is the major source of oxidative stress in endothelial cells (ECs) and is upregulated in diabetic retinopathy (DR). Increased cellular senescence has been observed in retinal blood vessels and contributes to DR pathogenesis. In this study, we investigated the role and mechanism of Nox4 in inducing retinal endothelial and vascular senescence in DR.

Methods: Primary brain microvascular endothelial cells (BMECs) and retinal microvessels (RMVs) were isolated from wild-type (WT) and humanized EC-specific Nox4 transgenic ($hNox4^{EC\text{-}Tg}$, referred to as TG) mice. Cellular senescence was evaluated by (1) senescence-associate β-galactosidase activity (SA-β-GAL); (2) expression of senescence-related genes quantified by quantitative real-time RT-PCR (qPCR); (3) senescence-associated secretory phenotype by measuring the secretion of IL-1β and hydrogen peroxide (H_2O_2) by ELISA or a H_2O_2 Assay Kit, respectively.

Results: TG-BMECs demonstrated a significantly increased number of SA-β-GAL positive cells compared with WT-BMECs. Consistently, expression of senescence markers including p21, Cdk6, Cdkn2a (p16) increased drastically in BMECs, and in RMVs, isolated from TG mice. Moreover, the levels of IL-1β and H_2O_2 secreted from TG-BMECs were significantly higher than that from WT-BMECs. To determine the mechanism of Nox4-mediated cellular senescence in ECs and retinal vessels, we examined mitochondrial biogenesis and the activating transcription factor 4 (ATF4)/p16 pathway, which have been linked to premature senescence in ECs and diabetic microvascular complications. We found that the expression of genes involved in mitochondrial biogenesis, including Opa1, Mfn2, Nrf1, Ppargc1β, and Tfam, was substantially decreased by 40-60% in TG-BMECs. A significant reduction in Mfn2 expression was also observed in RMVs from TG mice. Furthermore, overexpression of Nox4 led to an increased activation of the ATF4/p16 pathway. Inhibition of H_2O_2 by catalase or reducing oxidative damage by a potent radical-trapping antioxidant largely abolished Nox4-induced ATF4 activation and ameliorated senescent cells in TG-BMECs.

Conclusions: Overexpression of Nox4 induces endothelial and vascular senescence in the retina in part through impairing mitochondrial biogenesis and activation of the ATF4/p16 pathway, which may contribute to the development of DR.

ABSTRACT BODY:

Purpose: We present a descriptive study based on a series of cases where we measured the detection capacity and its characteristics using ultra-wide field retinography in patients with retinal tears and retinal detachments.

Methods: Ultra-wide-field retinographies were performed using confocal laser ophthalmoscopy Mirante (Nidek, Gmagori Japan) during the course of 1 month in all patients with a clinical diagnosis of retinal tear or retinal detachment who came to our ophthalmology department in the emergency department. We analyzed the demographic characteristics obtained in the clinical history, location of the tear and if it was visible, it is position 1 of the gaze using the tools of the Mirante platform and the area of detachment of the total retina with the ImageJ application (open source).

Results: A total of 14 patients were recruited; the average age was 65 years with a male / female ratio of 1.8 / 1. 43% (6) correspond to retinal tears and 57% (8) to retinal detachments (RD). In only 1 patient with RD, retinography could not be obtained due to media opacity. Both eyes were equally affected in a 1: 1 ratio. In 17% (1) of the tears it was possible to see them in the primary gaze position while 100% were visible in the secondary and tertiary gaze position, 100% of RDs could be seen in primary gaze position. 50% (3) of the retinal tears presented peri-tear fluid. On average, the tears were found 56° from the fovea, with the upper and lower temporal quadrants being the most affected, both 40% of the time and the upper nasal the remaining 20%. No primary lesions were found in the lower nasal quadrant. The average area of the detached retina with respect to the total retina seen in ultra-wide field retinography, in RD cases, was 68%. All the tears (100%) were treated by laser photocoagulation and 38% of the RDs (3) were treated by pars plana vitrectomy (PPV) plus silicone injection and the remaining 62% (5) by PPV and gas tamponade.

Conclusions: Ultra-wide-field retinography using cSLO is an excellent tool for detecting and characterize retinal tears and retinal detachments in clinical practice.

ABSTRACT BODY:

Purpose: To compare anatomical and functional outcomes of pars plana vitrectomy (PPV) with epiretinal membrane (ERM) peeling in diabetes mellitus (DM) patients with and without diabetic macular edema (DME).

Methods: A retrospective interventional case series of consecutive patients who underwent PPV with ERM peeling. Patients were divided into two groups: With and without preoperative DME. Visual acuity (VA) and optical coherence tomography (OCT) parameters were evaluated before surgery and during 12 months follow-up.

Results: A total of 354 patients underwent PPV with ERM peeling, of which 81 met the inclusion criteria. Twenty-three were diagnosed with DME and were younger (66.3±9.6 vs 75.1±8.5years, $p<0.001$), had longer DM duration (18.9±7.1 vs 14.3±11.4 years, $p=0.04$) and higher HbA1C% (7.6±1.4 vs. 7.0±1.1, $p=0.01$). VA improved from 20/105 to 20/60 Snellen ($p=0.004$) and central macular thickness (CMT) decreased from 469.3±64.9μm to 331.1±92.2μm ($p<0.001$) in the DME group and from 20/80 to 20/45 Snellen ($p<0.001$) and from 478.9±77.4μm to 353.1±64.1μm ($p<0.001$) in the non DME group. Yearly intravitreal injections rate decreased from 5.9±2.5 to 2.9±3.0 ($p<0.001$) injections in the DME group.

Conclusions: DME patients with ERM, experience significant improvement in VA, macular thickness and yearly intravitreal injections after PPV with ERM peeling. DME patients are younger, with lower VA, longer duration of DM and higher HbA1C% levels at presentation in comparison to diabetic ERM patients without DME.

ABSTRACT BODY:

Purpose: To assess functional outcomes and biomarkers changes after intravitreal dexamethasone implant (DEXI) in eyes with diabetic macular edema (DME), naïve and non-responders to vascular endothelial growth factor inhibitors (antiVEGF).

Methods: Retrospective real-world study conducted on consecutive DME patients with DEXI and were controlled at 2, 6 and 12 months. Subjects were divided in groups: naïve patients and non-responders to previously treated eyes with ≤3 antiVEGF injections (early switch) or >3 antiVEGF injections (late switch). Outcomes were best-corrected visual acuity (BCVA) and biomarkers with spectral domain optical coherence tomography (OCT) according to The European School for Advanced Studies in Ophthalmology (ESASO) classification and retreatments after DEXI.

Results: A total of 112 eyes were finally included in the study. At baseline, there were no statistically significant differences between gender, BCVA, CRT, type of diabetes mellitus, DME subtype and state of the lens. At month 2, the BCVA (logMAR) changed from 0.4 ± 0.52 to 0.35 ± 0.30, 0.52 ± 0.46 to 0.40 ± 0.52 and 0.70 ± 0.35 to 0.52 ± 0.44 in naïve, early and late switch group, respectively ($p<0.001$ between all groups). BCVA decreased at 6 and 12-month visit in naïve and early switch group and was stable in late switch from 6 month to final visit. Retinal thickness (T) improved at month 2, 6 and 12 in all groups ($p<0.001$). There was similar size cyst (C) reduction in all groups with statistically significant differences at 2 and 6-months ($p<0.001$ and $p=0.003$, respectively, between all groups). Presence of disorganization of the inner retinal layers (D) and subretinal fluid (F) improved at 12-month visit from baseline in all groups ($p=0.04$ at 6-month visit in both biomarkers). Hyperreflective foci (H) decreased in all groups over the study period ($p< 0.01$ at final visit). We found better results in D, F and H biomarkers over study period in late switch group. We did not found differences in the ellipsoid zone and/or external limiting membrane (E) and vitreoretinal relationship (V) alterations between groups in all time investigated. 89 (79.46%) eyes received additional treatment after first DEXI.

Conclusions: There were similar results in BCVA and biomarkers after DEXI in all groups with better findings in late switch group.

ABSTRACT BODY:

Purpose: Corneal trauma and infections have high morbidity requiring urgent intervention and close follow-up. Novel techniques are needed to improve patient outcomes, decrease surgical burden, and prevent blindness. Here we study the in vitro and ex vivo biocompatibility and regenerative capacity of a collagen-riboflavin hydrogel crosslinked by UV light.

Methods: We have developed a hydrogel consisting of collagen type I and 0.25 mM riboflavin-5-phosphate photo-crosslinked by UV (365nm) light. Epithelial and stromal integration was assessed by admixing cultured stromal cells within the hydrogel pre-cursor solution, exposing the complex to UV light, and seeding epithelial cells on the formed hydrogels. Confocal microscopy was used to visualize adherence and identify immunohistochemical markers associated with normal morphology. Epithelial wound healing over the hydrogel was also tested in ex vivo rabbit corneas. A 5mm anterior keratectomy was performed and a photo-crosslinked collagen-riboflavin hydrogel was placed in the defect. The organ culture specimen was then incubated for 72 hours and analyzed with confocal microscopy. All procedures were conducted on physically crosslinked collagen hydrogels without photo-crosslinking.

Results: Microscopy of the in vitro tissue showed adherence of epithelial cells to the hydrogel-stromal interface. Immunohistochemical staining was positive for IL-1β and TNF-α in epithelial and stromal layers. The epithelial cells also expressed Ki67, CD44 receptors, ZO-1, and CK12. In the organ culture model, the hydrogel was visualized in the keratectomy wound with overlying re-epithelialization after 72 hours. The corneal epithelium demonstrated a multi-layered epithelium as well as ZO-1 staining. The photo-crosslinked hydrogel showed faster epithelial growth in the in vitro model and both faster and morphologically superior re-epithelialization in the organ culture model compared to the physically crosslinked hydrogel.

Conclusions: Collagen hydrogels photo-crosslinked using riboflavin and UV light support epithelial cell growth in vitro and in ex vivo organ culture. Upon immunohistochemical analysis, corneal epithelial cells in the in vitro model expressed markers of epithelial phenotype and, in organ culture, exhibited multi-layered morphology. The photo-crosslinked hydrogel was superior in its ability to support epithelial cell growth compared to the physically crosslinked hydrogel.

Thomasy, Department of Ophthalmology & Vision Science, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure: Vanessa Rozo: Commercial Relationship: Code N (No Commercial Relationship) | Sangwan Park: Commercial Relationship: Code N (No Commercial Relationship) | Lamba Sangare: Commercial Relationship: Code N (No Commercial Relationship) | David Solis: Commercial Relationship: Code N (No Commercial Relationship) | Sara Thomasy: Commercial Relationship: Code N (No Commercial Relationship) | Jeroen Saeij: Commercial Relationship: Code N (No Commercial Relationship) | Brian Leonard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular involvement occurs in about 70-90% of patients infected with Toxoplasma gondii. The genetic determinants of T. gondii that allow the parasite to migrate across the blood-retinal-barrier are poorly understood. Identification of genetic factors are critical to understanding the pathogenesis of T. gondii and may provide novel strategies for therapeutic intervention. A previous large-scale screen identified the parasite secreted effector TgWIP as a potential candidate gene that influences parasitic migration to the eye. Upon invasion, T. gondii secretes TgWIP into the host cytosol and enhances dendritic cell motility and transmigration, potentially turning them into shuttling vectors of T. gondii to the eye.

Methods: CRISPR-Cas9 was used to generate T. gondii parasites lacking TgWIP (△TgWIP). CD-1 mice were infected with 200,000 parasites/mouse in 4 groups: wildtype (WT) intravenously (IV) (n=5), WT intraperitoneally (IP) (n=5), △TgWIP IV (n=5), △TgWIP IP (n=5). Mice were sedated, examined, and imaged at baseline and at 7 days post-infection (pi) using slit-lamp biomicroscopy, indirect fundoscopy, posterior segment optical coherence tomography (OCT), color fundus photography, and fluorescein angiography (FA). Animals were euthanized on day 7, globes were fixed and processed for histologic analysis and immunohistochemistry for identification of parasites.

Results: All animals survived to day 7 pi, however one mouse died from the WT IV group during imaging. Fundic photography demonstrated marked vasodilation pi in all treatment groups with △TgWIP IV infected mice having the greatest degree of retinal vessel dilation from baseline to day 7, followed by △TgWIP IP, WT IV, and WT IP. FA revealed poorly delineated vasculature at day 7 compared to baseline, indicative of increased vascular permeability. Moderate thickening of the choroid was evident on OCT at day 7 pi with △TgWIP infected animals demonstrating a significantly more pronounced thickening when compared with WT infected controls. Histopathologic analysis and immunolocalization of T. gondii are currently being performed.

Conclusions: All mice infected with T. gondii demonstrated vascular dilation and increased vascular permeability with a subjectively more significant effect in animals infected with △TgWIP irrespective of infection route. The role of TgWIP in parasite migration and inflammatory changes to the eye requires further investigation.

ABSTRACT BODY:

Purpose: SIRT1, a nutrient-sensing deacetylase, regulates various cellular stress responses. Loss of SIRT1 in the diabetic retina causes inflammation, neurovascular degeneration and visual impairment. Here, we investigated the effect of intravitreal administration of AAV2-SIRT1 on DR in a model of T2D, the db/db mouse.

Methods: After 6-months of diabetes, db/db mice were injected intravitreally with either AAV2-SIRT1 (AAV2-SIRT1-db/db) or control virus (AAV2-GFP-db/db) and euthanized three months later. SIRT1 upregulation was confirmed by RT-PCR and IHC. Caspase-3, Iba1, and GFAP expression were examined using IHC. Hypoxia Green reagent, a membrane-permeant, fluorogenic probe that can detect cells that are adapting to a hypoxic environment, and specific retinal cell surface markers were used for flow cytometry. ERG and OKN response measurements were undertaken to determine changes in retinal neural function and visual response, respectively.

Results: Retina of AAV2-SIRT1-db/db mice showed increased SIRT1 expression at mRNA (3.0±0.9 vs. 0.5±0.1, $p<0.05$) and protein (28.4±6.0 vs. 13.9±2.0, $p<0.05$) level compared to AAV2 GFP-db/db mice. $Iba1^+$ microglia were reduced in AAV2-SIRT1-db/db mice (4.0±1.0 vs. 9.0±2.0; $p<0.05$) compared to AAV2-GFP-db/db. GFAP reactivity in retinal macroglia of AAV2-SIRT1-db/db (869.9±30.0) was reduced compared to AAV2 GFP-db/db mice (1258±30.0; $p<0.01$). Caspase-3 positive cells were reduced in AAV2-SIRT1-db/db mice (15.0±5) compared to AAV2 GFP-db/db mice (8.0±3.0; $p<0.05$). Simultaneous detection of hypoxia and cell surface markers demonstrated that AAV2-SIRT1 administration reduced the number of hypoxic endothelial cells, bipolar cells, and photoreceptors compared to AAV2-GFP as assessed by flow cytometery. The scotopic b-wave (326.0±43.0) was significantly improved in AAV-SIRT1-db/db compared to AAV2 GFP-db/db mice (188.0±39; $p<0.05$). OKN responses were also enhanced in AAV2-SIRT1-db/db mice (0.39±0.01 vs. 0.28±0.02; $p<0.05$).

Conclusions: Intravitreal administration AAV2-SIRT1 reversed DR through inhibiting retinal inflammation and apoptosis, reducing the number of hypoxic retinal cells, and improving the function of retinal neural cells and visual responses.

ABSTRACT BODY:

Purpose: Adeno-associated virus (AAV) mediated gene augmentation therapy is the gold standard for treating inherited retinal dystrophies (IRDs). While, wild-type AAV integrates into a specific location in the human genome, other studies have shown extensive integration of recombinant AAV in other organs, but little is known about integration into the retinal genome. Due to the potential consequences of integration and increasing interest in AAV-mediated gene therapy, we used a high-throughput base-resolution approach to investigate this phenomenon.

Methods: Eyes of four one-month old mice were injected with 1×10^9 viral particles of pAAV-AcGFP. At 30 days, fluorescent fundus imaging was performed, mice sacrificed, eyes enucleated, and retinas removed and flash frozen. Retinal DNA was isolated and subject to the Agilent SureSelect XT HS2 DNA System using custom baits for the pAAV-AcGFP. Libraries were prepared and 2 x 150 bp sequenced on an Illumina HiSeq4000. Reads were aligned to the mm39 mouse genome with BWA-MEM, and integration sites were identified from discordant and split reads with at least 20 soft-clipped bases. Integration sites were RT-PCR validated.

Results: On average, 60 million reads were generated per sample, with 2.5 million discordant or split. We found 904 to 8,195 unique integration sites per animal, with 327 to 5,290 sites unique to an individual eye in one animal. In all, 105 exons and 1,072 introns contained AAV plasmid sequence, with the remaining sites intergenic; integrated plasmid sequence was typically a few hundred bases. Aside from suspected homologous recombination of the plasmid's β-globin intron in mouse hemoglobin genes, no other region was over-represented in integration sites, though we identified sequence fragments from the entire plasmid. Pathway analysis revealed various significant pathways among genes with plasmid integration, but none related to cell-cycle or other cancer-related pathways.

Conclusions: There is little overlap between integration sites in different animals, or between eyes of the same animal, suggesting AAV integration is largely random. Random integration opens the possibility that sites may occur in deleterious regions. Further, this raises concerns regarding multiple injections in IRD patients. Finally, we do not know the consequence of intragenic integration on expression or translation, though exonic integration likely causes frameshifts.

TITLE: Understanding Motivations and Barriers to the Use of Tele-Ophthalmology for Clinic-Based Visits Early in the COVID-19 Crisis

SESSION TITLE: Eyecare delivery and economics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Paranjpe, S. Massa, L.A. Al-Aswad, Department of Ophthalmology, NYU Langone Health, New York, New York, UNITED STATES|L.A. Al-Aswad, Department of Population Health, NYU Langone Health, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Vikram Paranjpe: Commercial Relationship: Code N (No Commercial Relationship) | Scott Massa: Commercial Relationship: Code N (No Commercial Relationship) | Lama Al-Aswad: Commercial Relationship(s);Code O (Owner):GlobeCheck;Code C (Consultant/Contractor):AI Optics, Topcon Medical Systems Inc, Aerie Pharmaceuticals Inc, Zeiss;Code F (Financial Support):New World Medical, Save Vision Foundation, Topcon Medical Systems Inc

ABSTRACT BODY:

Purpose: While tele-ophthalmology has existed in various forms as an adjunct tool in screening, diagnosis, and remote management, its adoption as a primary means of eye care delivery has been limited. The COVID-19 pandemic led to limited ability to provide in-person eye care and accelerated the need for tele-ophthalmology. This ongoing study seeks to understand patients' attitudes, motivations, and barriers to the use of tele-ophthalmology in lieu of in-person visits.

Methods: From March – October, 2020, in-person visits to a single university-based eye clinic were restricted to urgent ocular complaints. All routine visits were offered as video visits (VV) through the electronic medical record (EMR). 800 patients who completed a VV during this period, as well as a random selection of 800 patients who completed an in-office visit 6 months prior but no VV during this period, were sent an online survey. Data collected included demographic information, use of and comfort with digital devices, knowledge of the VV option, and reasons for use/non-use of the VV option.

Results: 35 individuals (54% male, 46% female; 80% White, 9% Black, 3% Asian, 9% other; mean age 63 ± 15 years) have participated in the study to date. 15 (43%) did not have a VV and 20 (57%) completed a VV. There were no significant differences in demographic factors between groups. 80% without vs 75% with a VV ($p>0.05$) felt somewhat or very comfortable using digital devices. 100% without vs 90% ($p>0.05$) with a VV were registered for the EMR patient portal prior to March 2020. Of the individuals who did not complete a VV, 25% did not want a VV for eye care, 25% were unaware of the VV option, 19% did not feel follow up was needed, 25% felt VV were insufficient for their eye care needs, and 1% reported lack of insurance coverage of VV as reasons for not choosing to complete a VV. Binomial logistic regression showed that demographic factors, comfort with digital device use, and prior access to the patient portal did not influence use/non-use of a VV.

Conclusions: The importance of tele-ophthalmology continues to increase as the COVID-19 pandemic threatens to limit feasibility of or patient willingness for in-person visits. An understanding of patients' attitudes towards and barriers to accepting video visits may help minimize disruptions in necessary eye care in case of future limitations in access to in-person services.

ABSTRACT BODY:

Purpose: Utilizing this unique opportunity to evaluate the majority of all children who seek eye care in Barbados, this study aims to determine the origin of referrals and age at first presentation to pediatric eye care centers in the public sector.

Methods: A retrospective, cross-sectional chart review of all patients under 18 years who sought eye care between Jan 1st and Dec 31st, 2019 at the two public eye care clinics in Barbados: Winston Scott Polyclinic, a primary care center (PCC) and Queen Elizabeth Hospital, a tertiary care center (TCC) in Barbados. Records with illegible handwriting or missing notes were excluded. The origin of referrals, age at the first visit to an eye care provider and relevant diagnoses were documented.

Results: Preliminary data was collected from 1,112 charts: 514 from TCC (10 months) and 598 from PCC (3 months). There was a statistically significant difference ($p<0.0001$) between the mean age of referral to TCC (3.6 ± 3.2 years) and PCC (8 ± 4.6 years) (Figure 1). 43% of the TCC referrals were initiated by interdepartmental referrals; 33% were referred from local polyclinics. School screenings constituted 69.2% of referrals to PCC (Figure 2). Referrals for retinopathy of prematurity (ROP) screening all occur at TCC between the ages of 1 and 7 months, with a mean of 2.2 months.

Conclusions: The pediatric population in Barbados has access to two public eye care centers, one PCC and one TCC. The difference between referral ages to the primary and tertiary care centers may be accounted for by the nature of visits. The TCC tends to see younger patients for conditions that may require immediate intervention (e.g., cataract management or ROP screening/management), while the PCC mainly receives referrals for refractive error assessment initiated by teachers' observations of students' behavior (e.g., difficulty seeing the board). The mean age of referral to PCC is 8 years, higher than recommended by the Guidelines for Development of Eye Care Programs and Services in the Caribbean, and the US Preventative Services Task Force, which emphasize the importance of eye screening at an early age. Further investigations should assess whether the later age of screening in Barbados negatively impacts visual outcomes.

ABSTRACT BODY:

Purpose: Vibrational optical coherence tomography (VOCT) supplements traditional optical coherence tomography with soundwaves to obtain the resonant frequency (RF) and the elastic modulus of anatomical structures. In this prospective study, we used VOCT to determine the in vivo elastic modulus of the human cornea.

Methods: Central corneal thickness measurements obtained from VOCT were correlated with those of Pentacam® (Oculus; Wentzler, Germany) pachymetry. VOCT measurements were performed at two different locations [central cornea (CC) and inferior cornea (IC)] in 32 normal eyes from 16 subjects. The RF and thickness values obtained from VOCT were employed in a calibration equation to calculate the corresponding modulus value. Repeated measurements were obtained in a subset of 10 eyes to assess the effect of anesthetic drops on the agreement of measurements.

Results: VOCT thickness values demonstrated a positive (r^2=0.97) and linear correlation (y = 0.939x - 13.92) to those of Pentacam. Five peaks (#1-5) were identified on the weighted displacement vs. frequency plots, although their presence was variable across eyes. The mean RF values for peaks #1-5 on the CC were 73.5±4.9, 120.4±2.0, 148.7±8.0, 207±7, and 239±3 Hz, respectively. The mean RF values for peaks #1-5 on the IC were 72.1±6.3, 120.3±1.8, 147.2±6.7, 205±7, and 238±4 Hz. Based on the corresponding RF, the calculated elastic modulus for peaks #1-5 on the CC were 1.023±0.104, 2.05±0.16, 2.94±0.40, 5.31±0.37, and 6.87±0.33 MPa, respectively. The IC elastic modulus for peak #1-5 were 0.975±0.150, 1.991±0.236, 2.76±0.28, 5.08±0.73, and 6.52±0.79 MPa. The effect of topical anesthesia in elastic modulus values for each peak was not significant ($p>0.05$), except for peak #2 in the CC ($p<0.05$).

Conclusions: This pilot study demonstrates the utility of VOCT as an in vivo, non-invasive technology to measure the elastic modulus in human corneas. The structural origin of the various moduli obtained can be hypothesized based upon reported in vitro studies, but further analyses are necessary for confirmation.

ABSTRACT BODY:

Purpose: Inhibition of dual leucine zipper kinase (DLK) and leucine zipper-bearing kinase (LZK) pathways promotes retinal ganglion cell (RGC) survival both in vitro and in vivo, but has limited effect on, and may even inhibit axonal regeneration. With the goal of finding ways to promote axonal regeneration of RGCs treated with DLK/LZK inhibitors, we investigated the effect of histone deacetylase inhibition and myosin inhibition on the neurite outgrowth of injured RGCs.

Methods: Human pluripotent stem cell-derived RGCs (hRGCs) were challenged with the microtubule-destabilizing agent colchicine and treated with a DLK/LZK inhibitor (tozasertib), an HDAC inhibitor (trichostatin A, TSA), and/or a myosin inhibitor (blebbistatin). After seventy-two hours, the viability of hRGCs was evaluated using a live cell stain (Calcein-AM), a dead cell stain (ethidium homodimer), and the ATP-based CellTiter-Glo assay. Neurite length and branchpoint number were quantified by high content screening. In addition to testing a wild-type stem cell line, a CRISPR-generated DLK/LZK knock-out hRGC line was also tested. The expression levels of genes of interest were determined by quantitative PCR.

Results: Although colchicine-induced hRGC cell death was inhibited by DLK/LZK inhibitor, tozasertib, the neurite length and the number of branchpoint were greatly reduced. The addition of the HDAC inhibitor TSA or the myosin inhibitor blebbistatin to colchicine/tozasertib treated hRGCs led to increases in neurite length and branchpoint number compared with colchicine/ tozasertib treatment alone. Combined treatment with TSA and blebbistatin led to further increases in neurite length and the number of branchpoint. Similar results were obtained in an hRGC line in which both DLK and LZK were knocked out. Furthermore, colchicine-induced reduction of expression of the RGC-specific genes BRN3A, RBN3B, THY1, and SOX11 was partially reversed by treatment with tozasertib, tozasertib/TSA, or tozasertib/blebbistatin.

Conclusions: In this study, we found that treatment with HDAC and myosin inhibitors increased neurite outgrowth in injured hRGCs which were concurrently treated with a DLK/LZK inhibitor. The effect of TSA and blebbistatin was additive. The combined inhibition of DLK/LZK, HDAC, and myosin suggests a possible therapeutic approach to repair injured RGCs.

ABSTRACT BODY:

Purpose: In the diagnosis of intraocular lymphoma, cytology with vitreous body samples has a low diagnosis rate because of the sparse number of cells and the destruction of cells during specimen preparation with conventional direct smear methods. Attempts have been made to improve the diagnosis rate by preparing cell block specimens. However, these are often difficult to prepare due to the availability of small quantities of samples. Liquid-based cytology (LBC) can increase cell accumulation by adsorbing atypical cells on the slide after fixation with a special fixation fluid. This can reduce cell destruction. We investigated the utility and safety of LBC for vitreous biopsy under perfusion in intraocular lymphoma.

Methods: Vitreous biopsy was performed on intraocular lymphoma (19 eyes in 15 patients) between 2015 and 2021 at Yamagata University Hospital. Vitreous body samples were obtained with 25-gauge vitrectomy under perfusion using a cut-rate of 8,000 rotations/min, and LBC specimens were prepared (BD SurePath, USA). After the vitreous biopsy, cell block specimens were prepared with the samples obtained from the perfusion pack.

Results: Atypical lymphocytes were identified in 14 of 19 eyes (73.7%) using LBC and in 13 of 19 eyes (68.4%) using cell block specimens. These atypical cells were also immunohistochemically positive for CD20 and Ki67. There were no complications during the vitreous biopsy under perfusion.

Conclusions: In diagnosing intraocular lymphoma, LBC for vitreous biopsy under perfusion is a useful and safe method that can achieve pathological diagnosis at a level comparable to cell-block specimens.

ABSTRACT BODY:

Purpose: Until now, methods for identifying compounds or genetic manipulations that alter the homeostasis of retinal proteins of interest (POI) have been limited mainly to non-physiologic constitutive overexpression of large fluorescent/luminescent reporter tags fused to that POI. Here we describe an attractive alternative strategy that allows for easy monitoring endogenously expressed POIs from retinal cells for unbiased drug/gene discovery.

Methods: As an initial proof-of-principle, we used a CRISPR/Cas9 ribonucleoprotein and ssODN HDR template to genome engineer immortalized RPE cells to express a 2xFLAG HiBiT tag (29 total residues) on fibulin-3 (F3, EFEMP1), a protein associated with Malattia Leventinese/Doyne Honeycomb Retinal Dystrophy and glaucoma. To detect the HiBiT tag, conditioned media or lysates were supplemented with LgBiT and substrate to generate NanoBiT (HiBiT + LgBiT), a bright and stable luciferase. Cells were used to efficiently screen ~10,000 compounds from the UT Southwestern chemical library. Toxic compounds and NanoBiT inhibitors were identified in counterscreens. Hit compounds were verified in dose-response, repurchased, and validated in differentiated/polarized primary porcine RPE cells to confirm their activity on F3 secretion/intracellular levels.

Results: Genome engineering of F3 resulted in the formation of a single 2xFLAG-tagged HiBiT species as detected by western blotting. LgBiT complementation of 2xFLAG HiBiT F3 in media enabled detection in sub-microliter volumes. Compound screening identified both F3 enhancers and reducers. Surprisingly, a series of drugs typically used for treatment of glaucoma significantly increased F3 expression whereas a set of compounds that can regulate epithelial to mesenchymal transition (EMT) signaling significantly reduced both secreted and intracellular F3.

Conclusions: These findings support the use of the versatile 2xFLAG HiBiT tag in retinal drug discovery. Such an approach can also be used to enrich (via the 2xFLAG peptide) endogenous POI interacting partners. We speculate that this same general approach can also be applied to other retinal degeneration genes and may ultimately be useful in identifying mutant-specific drugs or genetic manipulators.

ABSTRACT BODY:

Purpose: There is limited data available for the Canadian adult population diagnosed with anti-MOG. The goal of this study was to increase the understanding of the ophthalmic and neurological manifestations of anti-MOG disease in adults living in a Canadian setting through a retrospective/prospective chart review. With more information on the disease, clinicians can better identify these patients, understand the disease progression, and manage treatment options.

Methods: Data from standard of care ophthalmic and neurological assessments was collected over a 1-year period for patients who were diagnosed with Anti-MOG disease. Data collected includes patient demographics, ophthalmic assessment, neurological assessment, MRI and bloodwork results.

Correlation analysis was made between titer of MOG antibody and objective quantified ophthalmic findings, including electro-diagnostic results, MRI imaging, OCT imaging, and ophthalmic and neurological examination results.

Results: Five patients who were diagnosed with Anti-MOG have been tested. Of these, 60% were female and 40% were male, with ages ranging from 18 to 63 years old. On ocular examination the majority of eyes had normal visual acuity (60%). The remaining eyes had, 20/30, 20/50, hand motion and light perception vision (one eye each, 3 patients). On fundus examination, half the eyes showed signs of optic atrophy on RNFL testing. Vision loss was asymmetric as evidence by a relative afferent pupillary defect in the two patients with decreased vision. In patients affected with Anti-MOG with decreased visual acuity, pattern Visual Evoked Potentials were significantly reduced in amplitude. Other than the initial optic neuritis, one patient experienced no additional neurological effects, while the others experienced scintillating scotomas, recurrent mild paresthesia of both legs, and seizures. The MRIs displayed hyperintense T2 abnormalities in all patients.

Conclusions: The initial results of this study match existing literature for anti-MOG disease. Optic nerve atrophy is a commonly found ocular sign in patients with anti-MOG. Interestingly, patients were found to have decreased VEP amplitudes but normal inner and outer retinal function. The study recruitment is ongoing.

ABSTRACT BODY:

Purpose: A newly designed surface wettable silicone hydrogel (SiHy) contact lens material was studied based on sustained release of amphiphilic rewetting agent, EOBO [poly(oxyethylene)-co-poly(oxybutylene)]. The purpose of this study was to evaluate the uptake and release profiles of EOBO from the SiHy lens material.

Methods: The EOBO uptake profile into the lens matrix was evaluated with a fluorescence microscope using a fluorescent EOBO (Figure 1). EOBO release from the lens to a fixed volume of phosphate buffered saline (PBS) was measured with high-performance liquid chromatography (HPLC) at various times (Figure 2). Fick's second law and EOBO concentration measurements at equilibrium were used to obtain the diffusion coefficient and the partition coefficient of EOBO.

Results: Diffusion coefficient of EOBO measured was ~10^{-11} cm^2/s, which is about three to four magnitudes less than that of polymers with similar hydrodynamic radius. In addition, the lens partition coefficient of over 100 for EOBO indicated strong favorable interactions between EOBO and the hydrogel lens matrix. Lower molecular weight or more hydrophilic portion of EOBO preferentially released, whereas higher molecular weight or less hydrophilic EOBO practically retained within the bulk material. The unique interaction between the lens material and the rewetting agent contributed to the prolonged release of EOBO from the SiHy material. Results showed that EOBO released continuously from the bulk material for more than 7 days (Figure 2).

Conclusions: An in-vitro study and theoretical modeling were conducted on a new surface wettable SiHy contact lens material with a sustained release rewetting agent EOBO to demonstrate the feasibility of an enhanced re-wettable contact lens material. The unique interaction between the lens material and the rewetting agent contributed to the sustained release of EOBO from the SiHy lens material for more than 7 days.

ABSTRACT BODY:

Purpose: We previously reported on the neuroprotective activity of the lipid mediators, lipoxin A_4 and B_4 (LXA_4 and LXB_4). However, the downstream signaling cascades induced by these molecules in neuronal cells are still unclear. Here we aimed to develop a preliminary molecular signature describing LXA_4 and LXB_4 transcriptomic changes following treatment in neuronal cells.

Methods: Using next-generation sequencing, 4 treatment groups were analyzed: LXA_4, LXB_4,15-HETE (an inactive LXB_4 precursor) and Vehicle. The 15-HETE and Vehicle groups served as controls to identify genes specifically induced by each lipoxin treatment. HT22 neuronal cells were plated at $1x10^6$ cells per well in supplemented high glucose DMEM media and seeded overnight at 37°C. The following day, cells were treated with LXB_4, LXA_4, 15-HETE and Vehicle at 1µM in 4 biological replicates. Cell lysates were collected 1 hour after treatment, and total RNA was purified and seqeunced using an Illumina platform. Following sequencing, the data was bioinformatically sorted for differential gene expression analysis. Treatment groups were then fruther comparatively analyzed in R to identify lipoxin-specific transcripts.

Results: In comparison to vehicle 242 genes were identified specific to LXB_4 treatment, 539 for LXA_4, and 440 genes for 15-HETE treatment ($p<0.01$). Interestingly, only 23 genes were common between LXA_4 and LXB_4. In further analyses 15-HETE-specific genes were matched against LXA_4 and LXB_4 and common reads were removed to generate a molecular signature specific to each lipoxin treatment. The final unique gene counts were 185 and 315 genes with altered expression for LXB_4 and LXA_4 treatment, respectively.

Conclusions: A preliminary neuronal molecular signature for LXA_4 and LXB_4 signaling was identified, consisting of altered transcripts unique to each treatment. Next steps include ongoing characterization of the top hits under a variety of conditions and timepoints.

ABSTRACT BODY:

Purpose: We have previously shown that a 5-min eye-movement test can capture many largely independent “oculometric” parameters of human visual/visuomotor function (Liston & Stone, 2014). This test has been successfully used to characterize mild neural impairment due to traumatic brain injury, sleep and circadian disruption, and alcohol consumption (Liston et al., 2017; Stone et al, 2019; Tyson et al, 2021). Here, we extend this approach to study patients at risk of progressive posterior-segment illness to see how oculometrics relate to standard clinical ophthalmological measures.

Methods: Five female patients (≥20/40 BCVA, 34-60 years old) undergoing hydroxychloroquine treatment (2-7mg/kg/day for 10-23 years for rheumatologic illness) have participated thus far. Under monocular viewing conditions in randomized order, they tracked a moving spot undergoing radial step-ramp motion in 90 randomized directions, at 5 randomized speeds, starting at random times (see Stone et al, 2019). We computed nine independent oculometrics (latency, initial acceleration, steady-state gain, proportion smooth, saccadic rate, saccadic amplitude, direction noise, speed responsiveness, and speed noise). Spectral-domain optical coherence tomography (Zeiss, Dublin, CA) was used to measure the average thickness of the nine Early Treatment Diabetic Retinopathy Study macular sectors from the internal limiting membrane to the retinal pigmented epithelium. We used Pearson’s correlation between retinal thickness and our oculometrics with t-statistics to test separate one-sided hypotheses across 10 retinae.

Results: We found significant changes in different aspects of visuomotor performance. Most notably, latency increased, initial acceleration decreased, and steady-state pursuit gain decreased as retinal thickness decreased (r^2 = 0.364, 0.579, & 0.692; one-tailed P = 0.032, 0.005, & 0.001, respectively). Speed responsiveness appeared to decrease although marginally for our current sample (r^2 = 0.253, P = 0.069). Lastly, direction discrimination and saccadic behavior appeared unchanged.

Conclusions: Oculometrics may provide sensitive measures of changes in retinal thickness. More importantly, they have the potential to detect impairment before it becomes evident with standard clinical imaging, while also providing insight into the behavioral implications of any resulting deficits in visual/visuomotor function.

ABSTRACT BODY:

Purpose: AMD patients accumulate RPE mitochondrial DNA mutations. Furthermore, mitochondrial haplotypes, (e.g., haplotype J) are linked to AMD. In mice, increased expression of a dominant mutant polymerase gamma-subunit 1 ($PolG1^{D1134A}$) causes accelerated skin aging. We have reported that this mutant PolG1 increases mitochondrial DNA mutations, decreases mitochondrial genomes copies, lowers expression of antioxidant genes in ARPE-19 cells. Herein, we define the effects of mutant PolG1 expression in photoreceptors and RPE in C57BL6/J mice.

Methods: We injected C57BL6/J mice subretinally with 10^{10} vector genome copies of rAAV5, delivering either GFP or $PolG1^{D1134A}$ under the control of the small CBA promoter. We evaluated these mice's retina at one, two, and four months. We use electroretinography (ERG), spectral-domain optical coherence tomography (SD-OCT), and fundoscopy for each evaluation. After the final assessment, we euthanized these mice harvested their eyes. We used immunofluorescence to detect DNA damage (8-OHdG), changes in RPE65, and tight junctions (ZO-1). Finally, we used ultra-thin plastic sections to identify morphological changes within the retina.

Results: Mutant PolG1 expression in the retina decreased the a-, b-, and c-wave amplitude by 50% compared to GFP treated eyes beginning at one month after injection. The ONL of these mice was also significantly thinner when measured in SD-OCT images. Retinas cross-sections showed an abnormal distribution of RPE65 in mutant PolG1 treated mice. Flat-mounts co-stained with ZO-1 and 8-OHdG showed localized increase in oxidized DNA in animals treated with mutant PolG1. Ultra-thin retina sections of mutant PolG1 treated eyes showed accumulation of toluidine positive material under the Bruch's membrane, and death of RPE cells.

Conclusions: Our studies suggest that dominant mutant PolG1 expression in both photoreceptors and RPE cells results in accelerated retinal degeneration. This degeneration was characterized by a substantial decrease in retinal function (ERG response) and structure (SD-OCT, immunofluorescence, and ultra-thin sections). Future studies will elucidate the RPE and photoreceptors individual contribution to retinal degeneration due to mutant PolG1 expression, while also identifying changes in markers of accelerated aging in the retina.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRDs) are single-gene disorders caused by genetic mutations in any one of over 270 genes. Identifying the causative gene through genetic testing is crucial for gene targeted treatments, recruitment to clinical trials, prognosis and family planning. However the prescription and interpretation of genetic results requires phenotype-genotype recognition that only few IRD experts can provide. Therefore we aimed to develop Eye2Gene, an AI algorithm, to predict the probable IRD causative gene from the retinal scans of suspected IRD patients.

Methods: Eye2Gene was trained and tested on retinal scans of IRD patients with a known genetic diagnosis from Moorfields Eye Hospital (MEH). Following quality control, the MEH training dataset consisted of 44,817 images from 1,907 IRD patients from MEH, covering 3 modalities: Fundus Auto-Flourescence (FAF), Infrared (IR), and Spectral-Domain Optical Coherence Tomography (SD-OCT). For each of the 3 modalities, five distinct InceptionV3 convolutional neural networks (CNNs) were trained on different subsets of the training data using 5-fold cross validation to identify up to 36 gene classes. This resulted in Eye2Gene, an ensemble of 15 CNNs. Generalisability was assessed on a held-out dataset consisting of 264 patients from MEH and an external cohort of 37 patients from University Hospital of Bonn (UHB). To benchmark Eye2Gene against human performance, a subset 50 FAF scans were evaluated by 8 ophthalmologists.

Results: Eye2Gene yields a top-5 accuracy of 88% in the MEH held-out dataset and 83% in the external validation UHB dataset. On the human benchmarking dataset, Eye2Gene achieved a top-5 accuracy of 72% compared to 78% for ophthalmologists.

Conclusions: Eye2Gene is an AI algorithm capable of predicting the 36 top most common IRD genes to a top-5 accuracy of >80%. Eye2Gene achieves performance similar to a consensus of human experts on an external dataset. Eye2Gene can eventually enable democratisation of IRD expertise, currently only available in a few centres around the world.

ABSTRACT BODY:

Purpose: Lowe syndrome is a rare congenital disease that presents with renal failure, developmental delays, congenital cataracts, and glaucoma. The coordination between endocytosis dysfunction and the Akt/ mTORC1 signaling in Lowe syndrome patient cells is unclear. The present study tests the hypothesis that microtubule-based transport proteins are involved in the trafficking of lysosomes and maintenance of subsequent basal mTORC1 and Akt signaling. The relationship between endocytosis dysfunction and mTORC1/Akt signaling was also examined.

Methods: We examined mTORC1 and Akt signaling in normal human fibroblasts (NHF558) treated with nocodazole, which blocks microtubule polymerization, in complete culture medium. Activation of mTORC1signaling was assayed by the phosphorylation of p70 S6 Kinase (Thr389); activation of Akt signaling, by the p-ser473 Akt level. We also examined lysosome distribution in noncancerous cells in which Arl8a, Arl8b, SKIP, Rab7a or RLIP was knockdown by siRNA. Lysosome distribution was quantified by using average LAMP1 intensity.

Results: Knockdown of anterograde transport proteins small GTPase Arl8 or SKIP in normal human fibroblasts leads to perinuclear lysosome positioning and decreased mTORC1 signaling. However, Arl8 or SKIP knockdown in Lowe 1676 cells did not cause perinuclear lysosome accumulation and decreased mTORC1-mediated phosphorylation of p70 S6 Kinase (Thr389). Furthermore, we found that knockdown of retrograde transport proteins caused lysosomes to be scattered throughout the cytoplasm and decreased the perinuclear lysosome accumulation in normal human fibroblasts. However, we did not observe similar disruption in Lowe patient-derived fibroblasts with Rab7 or RLIP knockdown. Thus, these experiments show that mTORC1 and AKT signaling is sensitive to lysosome dynamics and that OCRL plays a role in the crosstalk between these pathways.

Conclusions: Whereas previous studies mainly focused on how transporters such as the kinesins and dynein motors regulate lysosome positioning, here we showed that the microtubule and actin systems themselves also play important roles in the transporting of lysosomes. These data suggested that under pathological conditions (e.g. congenital glaucoma), there are alternative pathways to regulate the mTORC1 and Akt signaling response to nutrient stimulus.

ABSTRACT BODY:

Purpose: We have previously shown that hindered phenol compounds have potent cytoprotective activity against oxidized low-density lipoprotein-induced death of retinal pigment epithelial cells (RPE) in vitro. The goal of this work was to determine the ocular pharmacokinetics (PK) as well as the therapeutic effect of a sustained-release solid lipid nanoparticle (SLN) formulation of the hindered phenol pentamethyl-6-chromanol (PMC) in two mouse models, in which characteristics of AMD are induced by aging and high fat diet.

Methods: PMC-loaded SLNs (SLN:PMC) were prepared by high-shear homogenization and delivered by periocular injection.For the PK study, total PMC in cornea/lens, retina, and RPE/choroid was determined by LC/MS analysis at 24 hours post-injection. For the efficacy study, 12-month-old wildtype C57BL/6J and APOE4-TR mice were fed with high fat diets (HFD) and treated weekly with SLN:PMC or empty SLN for five to six months. The eyes were then subjected to transmission electron microscopic analysis, or the RPE/choroid complex were used for gene expression analysis by semi-quantitative real-time PCR.

Results: A single periocular injection of PMC (969 ng in 5 ul) either as SLN:PMC or free drug achieved therapeutic levels of total PMC (~100 ng/tissue, 17 uM) in both the retina and RPE/choroid complex at 24 hours (n = 3-4 eyes/group). Five to six months of HFD in aged C57BL/6J and APOE4-TR mice resulted in significant sub-retinal deposits of drusen-like material, thickening and sometimes disruption of the Bruch’s membrane, and frequent signs of RPE degeneration. Weekly treatment with SLN:PMC (1 mM of PMC) resulted in reduction of sub-retinal deposits, preservation of the normal morphology of the Bruch’s membrane and RPE. Analysis of gene expression of the RPE/choroid did not reveal any significant changes to genes that are involved in RPE function comparing aged C57BL/6J mice with and without HFD and comparing HFD fed C57BL/6J mice without and without PMC treatment.

Conclusions: We have developed a sustained release SLN:PMC formulation which upon periocular injection achieved therapeutic levels of PMC in the back of the eye in the mouse. Preliminary experiments based on ultrastructural analysis suggested that SLN:PMC treatment was effective in reducing dry AMD-like pathologies in mouse models. These data support SLN:PMC as a potential therapeutic formulation for dry AMD.

TITLE: Cone spectral composition in the fovea
SESSION TITLE: Functional imaging and wavefront correction
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: V. Pandiyan, S. Schleufer, P. Bharadwaj, R. Sabesan, Ophthalmology, University of Washington School of Medicine, Seattle, Washington, UNITED STATES|
Commercial Relationships Disclosure: Vimal Prabhu Pandiyan: Commercial Relationship(s);Code P (Patent):University of Washington, Seattle | Sierra Schleufer: Commercial Relationship: Code N (No Commercial Relationship) | Palash Bharadwaj: Commercial Relationship: Code N (No Commercial Relationship) | Ramkumar Sabesan: Commercial Relationship(s);Code P (Patent):University of Washington, Seattle

ABSTRACT BODY:

Purpose: The fovea subserves high acuity vision by virtue of its densest packing of cone photoreceptors in the retina. Recent advances in high-resolution adaptive optics (AO) imaging have enabled detailing the distribution of foveal cones in humans, but their differentiation by spectral type has remained elusive. While it is known from anti-S-opsin staining that the proportion of short-wavelength (S-) cones decreases towards the foveal pit, the lack of immunostains for differentiating long and middle-wavelength (LM-) cones has made it impossible to ascertain their foveal distribution. Here we explore the spectral composition of the human fovea using an AO line-scan OCT-based optoretinogram.

Methods: A reflective mirror-based line-scan AO-OCT was used to image the fovea in two subjects. Volumes were recorded after 1-3 minutes of dark adaptation and a 660±10 nm bleach. The B-scan rate was 12 kHz and the field of view ranged from 1-1.6°. The volumes were reconstructed and registered. The optical phase change between the two reflections encasing the outer segment - the inner-outer segment junction, and outer segment tips - was calculated for each cone, and converted to optical path length (OPL). The change in OPL due to bleach was subjected to clustering analysis to distinguish cone spectral types. L:M-cone ratios and percent S-cones were calculated in the steps of 0.2° by 0.7° rectangular regions-of-interest in the range between 0.3° to 0.9° eccentricity along the 4 cardinal meridians.

Results:

The resolution was sufficient to visualize and spectrally classify cones 0.3° from the foveal center. Within 1° eccentricity, 9253 and 9115 cones were typed for subjects S1 and S2 respectively, with high accuracy. The proportion of S-cones increased with eccentricity; S1 : 2.2 to 6% and S2 : 3 to 8.9%. The rate of increase in S-cone proportion was the same in both, equal to 2.5 % per deg. The L:M cone ratio remained relatively stable within 1° eccentricity; S1 : 1.8 to 2.4 (Mean= 2.0), and S2: 1.2 to 2.0 (Mean = 1.5). No systematic difference was observed across the 4 cardinal meridians.

Conclusions: The first view of the human trichromatic cone mosaic in the fovea reveals an increasing S-cone proportion in line with prior reports, and a relatively stable L:M cone ratio. This has important implications for understanding the genetic mechanisms that control the photopigment expressed in cones and cell migration processes that occur during foveal development.

TITLE: Comparison of Brillouin Shifts Between Keratoconus, Post-LASIK, and Normal Control Corneas

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Asroui, H. Zhang, J.B. Randleman, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|G. Scarcelli, University of Maryland at College Park, College Park, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Lara Asroui: Commercial Relationship: Code N (No Commercial Relationship) | Hongyuan Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Giuliano Scarcelli: Commercial Relationship: Code N (No Commercial Relationship) | James Randleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the difference in Brillouin shifts between keratoconus patients, post-LASIK patients, and normal control patients.

Methods: Patients with keratoconus, post-LASIK patients, and normal control patients underwent imaging with Brillouin microscopy. The Brillouin shift was measured at multiple different points within the central 8mm of the cornea. Brillouin maps were then constructed for each cornea imaged using the data obtained. Comparisons between keratoconus and normal corneas, post-LASIK and normal corneas, and keratoconus and post-LASIK corneas were made.

Results: In the central 2mm, normal control corneas had a Brillouin shift of 5.7 GHz, which was higher than that of keratoconus corneas (5.6 GHz, p=0.001) and post-LASIK corneas (5.68 GHz, p=0.001). In addition, keratoconus corneas had lower Brillouin shifts than post-LASIK corneas (p=0.005). In keratoconus corneas, the difference in Brillouin shifts between the region of the cone and the peripheral “normal” regions was 60 MHz. In post-LASIK corneas, the difference in Brillouin shifts between the region of the ablation zone and the peripheral unaltered regions was 40 MHz. In normal control corneas, the difference in Brillouin shifts between the central 2mm and the peripheral cornea was less than 20 MHz.

Conclusions: Brillouin microscopy can effectively distinguish between keratoconus corneas, post-LASIK corneas, and normal control corneas.

ABSTRACT BODY:

Purpose: To investigate how the properties of choriocapillaris (CC) flow deficits (FDs) measurements in regions underlying drusen are affected by Bruch's membrane (BM) segmentation.

Methods: Swept-source optical coherence tomography angiography (SS-OCTA) imaging (PLEX® Elite 9000; Carl Zeiss Meditec, Inc, Dublin, CA) of eyes with age-related macular degeneration (AMD) were acquired using a 6x6 mm scan pattern. For a given OCTA scan, a reference surface corresponding to the location of BM was generated in several different ways, manually as well as using semi-automated and fully automated layer segmentation algorithms on B-scans. A completely automated algorithm used the OCTA scan and an associated BM surface as inputs to generate compensated CC slabs and binarized FDs maps, as described in several prior studies. Maps of local agreement between different FD maps of the same scan were generated by computing the absolute difference between the FD% within a small window centered at each pixel (Fig. 1C).

Results: Two graders manually segmented the full BM in 4 eyes with large confluent drusen. The mean absolute distance was 5.4μm between these surfaces over the regions where drusen were present. The FDs maps produced by the graders were qualitatively and quantitatively different, see Fig.1. On an additional set of 5 eyes, the graders manually corrected the BM in the regions under drusen. The resulting mean CC FD% under the drusen were significantly different between the graders. However, a well-trained, experienced grader can generate consistent measurements on different images of the same eye. When such a grader manually corrected the BM in the central region (1mm diameter) of 28 eyes with drusen, each imaged three separate times, the mean standard deviation of the CC FD% measurements was 2.3%.

Conclusions: CC FD maps can be strongly dependent on the exact shape and position of the BM surface used to segment them. In regions where the retinal pigment epithelium (RPE) geometry and its relation to BM are affected by an underlying pathology, as when drusen are present, the variability associated the BM surface segmentation and the resulting CC FDs maps can be substantial. In these cases, great care needs to be exercised in both the measurement process and the interpretation of results.

TITLE: The effects of vimentin knockout on corneal fibroblast mechanical behavior in 3D collagen matrices

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Miron Mendoza, E. Nakahara, M.P. Bhatt, J. Hulleman, M. Petroll, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Miguel Miron Mendoza: Commercial Relationship: Code N (No Commercial Relationship) | Emi Nakahara: Commercial Relationship: Code N (No Commercial Relationship) | Meet Bhatt: Commercial Relationship: Code N (No Commercial Relationship) | John Hulleman: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Petroll: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The intermediate filament vimentin has been linked to myofibroblast transformation of corneal keratocytes and the development of fibrosis during wound healing. Studies in other systems suggest it can also regulate key aspects of cell mechanical activity such as polarization, mechanosensing and focal adhesion dynamics. In this study, we investigate the role of vimentin on corneal fibroblast spreading in 3D culture.

Methods: A CRISPR/Cas9 RNP targeting vimentin was electroporated into human corneal fibroblasts, followed by screening to identify vimentin KO cell lines. Vimentin KO was verified by Western blotting and immunostaining. To assess cell spreading and mechanical activity, cells were embedded in 3D fibrillar collagen matrices. Samples were cultured for 4h or 24h in defined serum-free media (S-) or S- supplemented with PDGF BB (to stimulate cell spreading). 3D and 4D DIC imaging were used to assess cell mechanical behavior, global matrix contraction and live cell spreading. F-actin labeling was used to assess cytoskeletal organization and morphological changes.

Results: Both control (clone F11) and vimentin KO (clones F5 and G12) cells were able to spread and elongate within 3D collagen matrices in response to PDGF. Vimentin KO cells produced a similar percentage of matrix contraction as control cells (PDGF control = 33.3 ± 9.8; and PDGF KO = 37.2 ± 6.4; $P = 0.89$), and this was significantly higher than in S- media (S- control = 15.2 ± 3.0, $P = 0.049$ compared to PDGF; and S- KO = 11.4 ± 12.3, $P < 0.01$ compared to PDGF). Live cell imaging showed that during initial cell spreading in PDGF, all cell lines formed dendritic cell extensions that generated localized tractional forces by displacing collagen fibers. While the number of dendritic cell processes was similar (control = 15.3 ± 1.0; and KO = 13.2 ± 3.0, $P = 0.08$), motility and turnover of dendritic cell processes was more rapid in KO cells.

Conclusions: Corneal fibroblasts are able to spread, elongate and generate tractional forces in response to PDGF in the absence of vimentin within 3D collagen matrices. However, the increased activity and turnover of dendritic processes suggest underlying differences in the mechanics of cell spreading. The KO cell lines developed here should allow the role of vimentin in modulating corneal fibroblast behavior to be further assessed using a range of culture conditions and mechanical assays.

TITLE: The regulatory role of LOXL1-AS1 in gene expression

SESSION TITLE: Aqueous humor dynamics, IOP, corneal disease, cytokines and growth factors

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Hake, H. Schmitt, M.F. Suarez, K.M. Perkumas, M.A. Hauser, W.D. Stamer, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Kristyn Hake: Commercial Relationship: Code N (No Commercial Relationship) | Heather Schmitt: Commercial Relationship: Code N (No Commercial Relationship) | Maria Suarez: Commercial Relationship: Code N (No Commercial Relationship) | Kristin Perkumas: Commercial Relationship: Code N (No Commercial Relationship) | Michael Hauser: Commercial Relationship: Code N (No Commercial Relationship) | William Stamer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: LOXL1-AS1 is a long non-coding RNA associated with pseudoexfoliation glaucoma (PEXG). PEXG is characterized by the disrupted regulation of aqueous outflow and increased intraocular pressure. LOXL1-AS1 responds to mechanical stress, controls transcription, and patients with PEXG display fibrillary deposits in the eye; thus, we hypothesized that LOXL1-AS1 regulates genes involved in extracellular matrix (ECM) remodeling, cell adhesion, and mechanotransduction pathways in outflow cells.

Methods: LOXL1-AS1 was knocked down in primary cultures of human trabecular meshwork (TM) and Schlemm's Canal (SC) cells (4 strains each) using targeted Ad-shRNA in cells, and in human lens epithelial cells (HLE-B3) cells by transfection with a targeted siRNA. Knockdown (KD) verification and ECM gene expression were determined using qPCR or RNAseq. Genes with significant expression differences were further investigated using western blots, as were the mechanotransduction hub proteins, FAK, MAPK, pMLC, and AKT.

Results: Only data from experiments with >50% of LOXL1-AS1 knocked down was analyzed. In HLE-B3 cells with LOXL1-AS1 KD, 7 genes were significantly altered ($p<.05$). Thrombospondin 2 and Tenascin C were upregulated by 2-fold ($p<.05$) while TIMP1 decreased by 50% ($p<.05$). After KD of LOXL1-AS1 in TM cells, the expression of 7 ECM genes were significantly altered ($p<.05$). Of these, col11α1 showed a 50% decrease in expression and integrinβ3's expression doubled ($p<.05$). Genes affected by LOXL1-AS1 KD in TM were Col6α6 (4-fold increase, n=3, p=.04) and Col3α1 (1.5 fold increase, n=3, p=.001). When LOXL1-AS1 was KD in SC cells, 13 genes showed significantly altered RNA expression. Of these, integrinα2 was upregulated by 2.5-fold and lamininλ1 decreased by 50% ($p<.05$), but protein validation did not show a significant change. Of the mechanotransduction proteins analyzed, the phosphorylation of AKT was significantly elevated in SC cells (n=4, p =.008), and trending toward elevation in TM cells (n=4, p=.056).

Conclusions: LOXL1-AS1 regulates many genes in a cell type-dependent manner. For outflow cells, LOXL1-AS1 controls the expression of key ECM components and AKT, a central mechanotransduction protein. Thus, polymorphisms in LOXL1-AS1 may contribute to fibrillary deposits, cell signaling, and/or ECM homeostasis in the conventional outflow pathway of the eye of PEXG patients.

TITLE: Topical and systemic administration of FDA-approved GLP-1R Agonists rescue retinal ganglion cells in hypertensive glaucoma

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Lawrence, M. Guo, J. Wong, T. Schwartz, J. Wu, J. Lu, J. Sterling, J.L. Dunaief, Q.N. Cui, Ophthalmology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Emily Lawrence: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Guo: Commercial Relationship: Code N (No Commercial Relationship) | Johnathan Wong: Commercial Relationship: Code N (No Commercial Relationship) | Turner Schwartz: Commercial Relationship: Code N (No Commercial Relationship) | Jie Wu: Commercial Relationship: Code N (No Commercial Relationship) | Jingwen Lu: Commercial Relationship: Code N (No Commercial Relationship) | Jacob Sterling: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Dunaief: Commercial Relationship: Code N (No Commercial Relationship) | Qi Cui: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The centrally-acting GLP-1R agonist NLY01 reduces microglial/macrophage activation and rescues retinal ganglion cells (RGCs) in a mouse model of hypertensive glaucoma (PMID33147455). Clinically-available GLP-1R agonists are also associated with a reduced risk for glaucoma in diabetic patients (PMID34413054). In this study, we examined whether FDA-approved GLP1R agonists, administered either topically or systemically, prevent RGC loss and decrease neuroinflammation in an mouse model of hypertensive glaucoma.

Methods: Three-month old C57BL/6J mice were injected with either microbeads or BSS. IOP was measured weekly and remained elevated in bead-injected eyes for 7 weeks. GLP-1R agonists were initiated within 3 days of ocular injection and administered either twice daily topical (lixisenatide 20µg/kg/day or liragutide 400µg/kg/day) or twice weekly subcutaneous (liraglutide 400µg/kg/day or NLY01 5mg/kg/injection). At the end of 7 weeks, retina flatmounts were immunolabeled for RBPMS and Iba1 to quantify RGC and myeloid cell density, respectively. Quantitative PCR assessed pro-inflammatory cytokine expression in cellular populations enriched for either macrophage/microglia or astrocytes. Microelectrode array recording of dark and light-adapted retinas functioned to characterize RGC function. RGC axons were quantified using optic nerve cross sections.

Results: Compared to bead-injected eyes treated with topical liraglutide, RGC density was 24% lower in bead-injected untreated eyes ($p=0.0048$). Similarly, topical lixisenatide was associated with 29% RGC rescue following IOP elevation ($p=0.0096$). Subcutaneous liraglutide and NLY01 injections resulted in complete RGC rescue after IOP elevation. While myeloid cellular density trended up following microbead injections, differences were not significant and remained comparable before and after treatment with topical and systemic agents. Pro-inflammatory cytokine expression, RGC function, and axon quantifications are pending.

Conclusions: Topically and systemically administered GLP-1R agonists improved RGC survival following IOP elevation. The number of activated myeloid cells in the retina were not significantly affected by GLP-1R agonist treatment in this experiment.

Commercial Relationships Disclosure: John Bladen: Commercial Relationship: Code N (No Commercial Relationship) | Ziyaad Sultan: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Brady: Commercial Relationship: Code N (No Commercial Relationship) | George Mikhaeel: Commercial Relationship: Code N (No Commercial Relationship) | Jon Salisbury: Commercial Relationship: Code N (No Commercial Relationship) | Steve Connor: Commercial Relationship: Code N (No Commercial Relationship) | Stella Bowcock: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Evaluating a new, comprehensive orbital lymphoma service. A prospective case series was carried out to evaluate the pathway and to identify common themes in orbital lymphoma

Methods: 20 patients (mean age 67 SD14.4; M:F 1:1). presented to ophthalmology over 2 years, were managed on a pathway involving MDT care across ophthalmology, haematology, pathology, oncology and radiotherapy. Baseline investigations included MRI orbits, half-body PET-CT scan, FBC, U&E, Calcium, LDH LFT, ESR, HIV, Hepatitis B&C, open orbital biopsy and bone marrow biopsy. Patients were recorded under AJCC v8 TNM for ocular adnexal lymphoma and Ann-Arbor (AA) staging systems. All patients were discussed at the weekly haematology-oncology MDT on confirmation of histological diagnosis. Those undergoing radiotherapy have an imaging response assessment at 3 months with subsequent long-term follow-up under joint haematology-ophthalmic care

Results: The pathway was completed by 16 cases, 1 case was palliated prior to biopsy, 1 had a diagnostic pancreatic biopsy, 2 followed up elsewhere. Commonest presentation was ptosis (5), palpable mass (4), proptosis (3), conjunctival lesion (2) and epiphora (2). Two had contiguous, bilateral orbital disease. Histology: 11 EMZL, 4 DLBCL, 1 SLL. Bone marrow involvement in 1 EMZL and 1 DLBCL. Doxycycline had no effect on 2 conjunctival lesions. Mean time from biopsy to treatment (radiotherapy or chemotherapy) 61 days. Radiotherapy was given to 11 (4-30Gy). DBCL received 3 cycles of R-CHOP. 15 had radiologic remission with 1 contracted lesion considered remission

Conclusions: A multi-disciplinary approach is essential in managing orbital lymphoma. Doxyxycline had no effect and higher doses of radiotherapy was required in some EMZL. Bone marrow biopsy is essential for staging. Having expertise within each area provides a comprehensive patient experience, however coordination between multiple sites and locations can pose difficulties in running a smooth and timely pathway

ABSTRACT BODY:

Purpose: Traumatic brain injury (TBI) is a condition with devastating lifelong consequences. Visual photosensitivity is a common and incapacitating symptom associated with TBI. The purpose of our study was to assess visual photosensitivity in healthy and TBI study participants using the Ocular Photosensitivity Analyzer (OPA, Aguilar et al. BOE 2018, 9(11): 5583-5596).

Methods: Twenty-five healthy study participants (13 females and 12 males, age = 32.5±13.3) and nine TBI study participants (2 females and 7 males, age = 35.7±14.5) were tested using the OPA under an IRB approved protocol. The automated OPA produces light stimuli of varying intensities utilizing unequal ascending and descending steps. Each stimulus is presented for 2 seconds, followed by a rest period of 4 seconds. The subject is instructed to indicate whether the light stimulus is “uncomfortable” by pressing a hand-held button. The visual photosensitivity threshold (VPT) is calculated from the mean of 10 response reversals. A higher VPT indicates more tolerance to light while a lower VPT indicates less tolerance to light. Additionally, study participants were administered the Visual Light Sensitivity Questionnaire-8 (VLSQ-8), prior to being tested with the OPA, to assess the presence and severity of visual photosensitivity symptoms. The VPT and VLSQ-8 scores of healthy and TBI study participants were compared.

Results: The VPT of healthy and TBI study participants were 2.5±0.8 and 1.6±0.9 log lux, respectively, $p<0.05$. VLSQ-8 scores of healthy and TBI study participants were 11.6±3.3 and 20.7±8.9, respectively, $p<0.05$. VPT scores were negatively correlated with VLSQ-8 scores ($r=-0.56$, $p<0.01$).

Conclusions: Visual photosensitivity was assessed in healthy and TBI study participants using the OPA. Healthy study participants had higher VPT and lower VLSQ-8 scores compared to TBI study participants. Quantitative clinical outcome measures are needed in TBI to better characterize disease severity, monitor progression, and evaluate efficacy of emerging treatments.

TITLE: The role of Notch 3 in maintaining retinal vascular stability during aging

SESSION TITLE: Molecular events in diabetic retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. O'Hare, J. Arboleda-Velasquez, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|M. O'Hare, J. Arboleda-Velasquez, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Michael O'Hare: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Arboleda-Velasquez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Notch signaling plays a critical role in vascular development, regulating fundamental processes such as angiogenesis, arterial/venous differentiation, and mural cell investment. However, aberrant Notch signaling can result in severe vascular phenotypes as observed in cerebral arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) and has been implicated in pericyte loss during diabetic retinopathy. An interesting question remains regarding the changing requirement for Notch signaling during aging. It is evident that Notch 3 signaling plays an important role in the differentiation of mural cells during development, yet it remains unclear how these interactions are affected during aging and how this affects retinal vascular stability.

Methods: Two knockin mouse lines were generated expressing human Notch 3 with or without the C455R CADASIL mutation expressed under an SM22-cre in a Notch 3 knockout (N3KO) background and aged to 24 months. Fluorescein angiography was carried out at 6, 12 and 24 months. Immunolabelling was carried out on cryosections and flat-mounted retinas assessing changes in the vascular, glial and neuronal retinal components. Transmission election microscopy (TEM) was used to assess changes in microvascular structure.

Results: We report that the C455R mutation in Notch 3 causes a significant reduction in retinal vascular stability in an age dependent and dominant negative manner. C455R mutant mice displayed increased vasopermeability and retinal vascular caliber at 24 months ($P<0.05$). Interestingly, we also report that N3KO mice develop retinal vascular aneurysms at 24 months of age, this phenotype can be rescued through the expression of wild type Notch 3 in mural cells.

Conclusions: These data have shown for the first time a requirement for Notch 3 in the aging vasculature and that the expression of the C455R mutation results in an increase in vasopermeability in the retina at 24 months. Whereas, mice expressing wild type Notch 3 rescued the phenotype of N3KO mice. These findings may hold importance for retinal vascular diseases such as diabetic retinopathy in which alternations in Notch 3 expression have been reported and warrants further investigation.

TITLE: Agreement Between Functional History and Plan of Care in Low Vision Rehabilitation

SESSION TITLE: Quality of Life Outcomes, Rehabilitation and Training Programs

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.L. Brown, C. Bradley, R.W. Massof, G. Dagnelie, J.E. Goldstein, Ophthalmology, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Dominic Brown: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Robert Massof: Commercial Relationship: Code N (No Commercial Relationship) | Gislin Dagnelie: Commercial Relationship: Code N (No Commercial Relationship) | Judith Goldstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: For successful low vision rehabilitation (LVR), the clinician's plan of care (POC) should agree with the patient's functional visual goals. A retrospective review of patient records tests this premise by determining the level of agreement between patients' functional histories (FH) and their POCs. Further, this study aims to explore the application of functional domain classifications as a method of classifying elements in the FH of the patient, and estimating how well the provider's POC addresses those elements.

Methods: As a feasibility study, we analyzed the FH and POC of 20 consecutive new patients at the Wilmer Eye Institute Lions Vision Rehabilitation Service. The FH was reviewed and each element assigned to one of 11 functional domains, 10 from the Dutch Activity Inventory (PMID: 21090911) and an 11th (glare) that we created. The proportion of the domains identified in the FH that were addressed in the POC was calculated and served as the dependent variable. Pearson correlations between the dependent variable and age, best-corrected visual acuity of the better seeing eye (BCVA), and contrast sensitivity (CS) were estimated for the sample of patients.

Results: Of the 20 records included in this feasibility study, 50% of patients had 100% agreement between functional domains identified in the FH and POC. The other half had levels of functional domain agreement uniformly distributed from 18%-91%. The overall mean (SD) level of functional domain agreement was 78% (28%). The correlation between the level of agreement and age in our sample was -0.38. The most common domains documented in the FH were learning and applying knowledge (90%), mobility (50%) and glare (50%). The least common were self-care (0%), general tasks and demands (10%), and community/social/civic life (30%).

Conclusions: The distribution of the levels of functional domain agreement found in this study demonstrates the feasibility of the described approach in determining how thoroughly clinicians address the needs of patients. Our method provides a means of retrospectively determining the level of functional agreement between FH and POC that otherwise cannot be done in the absence of structured questionnaires. This is an ongoing study, which will expand towards evaluating various methods of retrospectively categorizing elements in the FH and POC.

TITLE: The Effect of Blue-light-blocking Intraocular Lenses on Sleep, Mood, and Circadian Rhythm in Diabetic Patients

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Adams, O. Iqbal, J. McDonnell, Ophthalmology, Loyola University Health System, Maywood, Illinois, UNITED STATES|R. Hakim, Loyola University Chicago Stritch School of Medicine, Maywood, Illinois, UNITED STATES|M. Wesolowski, Clinical Research Office, Loyola University Health System, Maywood, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Nolan Adams: Commercial Relationship: Code N (No Commercial Relationship) | Ryan Hakim: Commercial Relationship: Code N (No Commercial Relationship) | Omer Iqbal: Commercial Relationship: Code N (No Commercial Relationship) | Michael Wesolowski: Commercial Relationship: Code N (No Commercial Relationship) | James McDonnell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to investigate the effect of blue-light-blocking intraocular lens (IOL) versus non-blue-light-blocking IOL placement during cataract surgery on sleep, mood, and Circadian rhythm in diabetic patients. Placement of a blue-light-blocking IOL may reduce exposure of the intrinsically photosensitive retinal ganglion cells to blue light, inhibiting the ability of these cells to synchronize the body's Circadian rhythm, which may in turn affect sleep patterns and mood.

Methods: We recruited 20 patients diagnosed with diabetes mellitus type 2 who were scheduled to undergo bilateral cataract surgery. Patients filled out the SCRAM (Sleep, Circadian Rhythms And Mood) Questionnaire before cataract surgery and again 1-3 months after cataract surgery. Changes in SCRAM Questionnaire answers before and after surgery were assessed to estimate the effect of IOL type.

Results: In diabetic patients undergoing bilateral cataract surgery, across all types of IOL, SCRAM Questionnaire scores for Good Sleep increased by 3.39 (P = 0.45), Morningness increased by 0.08 (P = 0.98), and Depressed Mood decreased by 3.61 (P = 0.21). When patients receiving ultraviolet-light-blocking IOLs were compared to those receiving blue-light-blocking IOLs, their scores for Good Sleep increased by 7.99 less (P = 0.11), Morningness increased by 10.70 more (P = 0.17), and Depressed Mood decreased by 0.82 less (P = 0.72).

Conclusions: These results suggest that cataract surgery may result in subjectively improved sleep quality and mood regardless of the type of IOL placed, although results were not statistically significant. No statistically significant improvement in sleep quality, Circadian rhythm, and mood was shown in patients receiving blue-light-blocking IOLs as compared to those receiving ultraviolet-light-blocking IOLs.

AUTHORS/INSTITUTIONS: S. Shirahama, M.S. Gregory-Ksander, B. Ksander, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|S. Shirahama, M.Y. Lee, Y. Okunuki, K.M. Connor, M.S. Gregory-Ksander, B. Ksander, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|M.Y. Lee, Y. Okunuki, K.M. Connor, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Shintaro Shirahama: Commercial Relationship: Code N (No Commercial Relationship) | May Lee: Commercial Relationship: Code N (No Commercial Relationship) | Yoko Okunuki: Commercial Relationship: Code N (No Commercial Relationship) | Kip Connor: Commercial Relationship: Code N (No Commercial Relationship) | Meredith Gregory-Ksander: Commercial Relationship: Code N (No Commercial Relationship) | Bruce Ksander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Understanding the function of MHC class II positive (MHC-II+) antigen-presenting cells (APCs) is critical in understanding the pathogenesis of uveitis, which has two potential sources of APCs, retinal microglia and systemic macrophages. We previously published evidence that MHC-II+ microglia are not required for the induction of uveitic specific T cells. In the current study, we determine whether MHC-II+ microglia exacerbate uveitis by activating retina-infiltrating T cells.

Methods: EAU was induced by IRBP immunization of C57BL/6 mice, and the clinical score was determined by the standard method. FACS analysis was used to determine MHC-II expression on microglia (TMEM119 and P2RY12 antibodies). Knock-down of MHC-II specifically on microglia and not on systemic macrophages was achieved using an inducible knockout mouse (Tmem119-CreERT2 x MHC-II$^{flox/flox}$ B6 mice; Tmem119-Cre KO mice) in which deletion of MHC-II was induced by tamoxifen and confirmed by FACS analysis. Adoptive transfer EAU was induced by harvesting T cells from the spleen and lymph nodes of donor mice at 14 days post-IRBP immunization and injecting i.p. (5×10^7 cells/mouse) into naïve recipients.

Results: During the first 10 days after induction of EAU, there was no increase in MHC-II+ retinal microglia (1.1 +/- 0.3%) as compared with retinas of naïve mice (0.7 +/- 0.3%). By contrast, in the later stage of EAU (day 20), there was a significant increase in the number of MHC-II+ Tmem119+ microglia (56.8 +/- 1.0%) within the retina. Similar results were obtained using P2RY12, another microglia specific antibody. Removal of MHC-II specifically from these retinal microglia and not from macrophages using inducible Tmem119-Cre KO mice significantly reduced the severity of the disease when the clinical score was compared with the frequency of MHC-II+ microglia ($r=0.78$, $p=0.0036$). To further confirm this, uveitic T cells from IRBP immunized WT mice were adoptively transferred into either MHC-II$^{flox/flox}$ or Tmem119-Cre KO mice, resulting in a significant delay in the development of uveitis ($p=0.03$).

Conclusions: Our data indicate that MHC-II+ retinal microglia do not participate in the induction of uveitis but are important in the later stages where they exacerbate disease by activating retina-infiltrating T cells.

ABSTRACT BODY:

Purpose: To investigate color perception in patients with diabetic macular edema (DME) assessed with a new digital color test and with pseudoisochromatic plates and explore the correlation with optical coherence tomography (OCT) parameters.

Methods: Twenty-nine patients (n=29 eyes) with DME and mean age of 70.2 years (SD=6.8) were retrospectively included. Color vision was evaluated in all subjects using the H-R-R, the Ishihara Test (38 plates) and the digital color test. The total number of correct plates was measured for each test and assessed in correlation with OCT parameters: Central Macular Thickness (CMT), Volume Cube (VC) and Total Average Thickness (TAC). The new color test records the level of brightness needed to detect color targets of red, green and blue hues and results were also correlated with these OCT parameters. Spearman correlation coefficient was computed for estimating correlations among CMT values and results of the color tests.

Results: The mean visual acuity was 0.60 (SD 0.30) logMAR and the mean CMT, VC and TAC values were 429.5 μm (SD 129.9), 11.9 mm^3 (SD 3) and 330.1 μm (SD 82.9), respectively. All participants demonstrated color vision defects in all color tests; in the Ishihara (Mdn=3.0 plates, IQR: 1.0-20.0), in the H-R-R (Mdn=2.0 plates, IQR: 0.0-4.8). Regarding the new digital color test, increased needs for brightness in red (Mdn=28.0%, IQR: 24.0-31.0), green (Mdn=20.0%, IQR: 15.5-25.0) and blue (Mdn=26.0%, IQR: 21.5-31.0) colored targets were also detected. The CMT values were significantly ($p<0.05$) correlated with the brightness values in the blue targets. Specifically, more brightness was required for the detection of the blue targets in individuals with increased values of CMT.

Conclusions: Color vision was found to be affected in patients with DME and should be evaluated as a useful part of a comprehensive ophthalmological examination. Furthermore, this study presents preliminary evidence of the efficacy of a new digital color test to detect deficits in patients with diabetic macular edema.

TITLE: Transepithelial Crosslinking Using Femtosecond Laser Machined Epithelial Microchannels for Riboflavin Delivery

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Bradford, R. Joshi, Y. xie, D. Brown, T. Juhasz, J.V. Jester, S.B. Han, Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|R. Joshi, T. Juhasz, J.V. Jester, Biomedical Engineering, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Samantha Bradford: Commercial Relationship: Code N (No Commercial Relationship) | Rohan Joshi: Commercial Relationship: Code N (No Commercial Relationship) | yilu xie: Commercial Relationship: Code N (No Commercial Relationship) | Donald Brown: Commercial Relationship: Code N (No Commercial Relationship) | Tibor Juhasz: Commercial Relationship: Code N (No Commercial Relationship) | James Jester: Commercial Relationship: Code N (No Commercial Relationship) | Sang Han: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ultraviolet corneal collagen crosslinking (UVA CXL) via photoactivation of riboflavin (Rf) is an effective treatment for Keratoconus, and in development as a refractive procedure. A drawback of UVA-CXL is the need for epithelial debridement to achieve adequate stromal Rf concentrations, leading to discomfort, delayed recovery, and risk of infection. Transepithelial (TE) CXL using chemical disruption of the corneal epithelial barrier has been shown to have limited success in addressing these concerns. Also an intact epithelium could act as a barrier to irradiation, preventing effective TE UVA-CXL. This study describes a femtosecond laser (FS) approach to machine corneal epithelial microchannels (MC) for enhanced stromal Rf penetration combined with nonlinear optical (NLO) CXL to avoid both epithelial damage and shielding of irradiation.

Methods: Using a 1030nm FS laser with 5μJ pulses, 2μm diameter by 25μm long MC were machined into the epithelium of ex vivo rabbit corneas at a density of 100 MC/mm^2. Rf penetration through the MC was then determined by applying 1% Rf in PBS with osmolarity ranging from 200-450 mOsm for 30 minutes followed by removal of the cornea and extraction from the central stromal button. Stromal Rf concentrations were compared between osmolarity groups. Eyes treated with MC UVA-CXL were compared to eyes treated with BAK UVA-CXL using collagen autofluorescence (CAF) to determine the effect of CXL. CXL was performed both with and without continuing drops of Rf solution to determine the shielding effect of the solution on the surface of the eye.

Results: Rf levels were highest in eyes treated with 250 mOsm solution. No eyes treated with TE UVA CXL with continued dripping produced measurable CAF in either group. Eyes without further dripping after the start of CXL did produce CAF. Additionally organ culture showed a normal corneal epithelium following both MC alone and MC NLO CXL, while BAK alone, BAK UVA CXL, and MC UVA CXL treated corneas all showed extensive epithelial and stromal damage at 24 hours post treatment.

Conclusions: FS epithelial MC enhance stromal penetration of Rf for corneal CXL, but both the epithelium and a layer of Rf solution shield the cornea from UVA irradiation, inhibiting CXL. Data suggests that combining MC with NLO CXL minimizes damage, avoids shielding, could lessen patient discomfort, speed recovery, and decrease risk of infection.

TITLE: Fixation Stability for Emmetropic and Myopic Patients as a Function of the Target's Frequency Content
SESSION TITLE: Myopia and refractive error development
SESSION TYPE: Paper Session
AUTHORS/INSTITUTIONS: P. De Gracia, Chicago College of Optometry, Midwestern University - Downers Grove Campus, Downers Grove, Illinois, UNITED STATES|A. Wazir, Z. Goodman, E. Ong, Midwestern University Chicago College of Osteopathic Medicine, Downers Grove, Illinois, UNITED STATES|
Commercial Relationships Disclosure: Pablo De Gracia: Commercial Relationship(s);Code C (Consultant/Contractor):Lentechs;Code F (Financial Support):CooperVision;Code F (Financial Support):MarkEnnovy | Azra Wazir: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Goodman: Commercial Relationship: Code N (No Commercial Relationship) | Emily Ong: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To describe fixation stability in emmetropic and myopic subjects through focus as a function of the frequency content of targets.
Methods: In order to identify the patterns of FEMs (microsaccades) of emmetropic, myopic, and hyperopic subjects, we measured the binocular fixational eye movements of 35 subjects (7 emmetropic or low hyperopes, 28 myopic) with an eye tracker (EyeLink 1000). We did this for three targets: natural image (NI), Maltese cross (MC), and 20/40 letter E (LE). And 11 levels of blur (+5D and -5D in 1 D steps). A total of 33 trials were recorded per subject. Each complete session of measurements for one subject lasted between two and three hours. The order of the conditions was randomized across subjects.
The optical system is formed by an Eye Tracker attached to an optical system that allows representing different vergence levels (without introducing magnification) through two motorized Badal systems with a precision of 0.01D. Also, this optical system also allows to precisely control pupil sizes. Pupil sizes were set to 4 mm by controlling a physical aperture placed in a conjugated plane to the eye’s pupil plane: this allowed for constant retinal illumination across subjects. For each trial, the EyeLink recorded binocular eye movements during two minutes at a rate of 1,000 measurements per second. If needed, subjects were corrected for their natural refractive error using contact lenses to standardize the baseline level of blur at 0 D.
Results: Microsaccades were identified and analyzed following the Engbert and Kliegl model (2003). More than 150,239 binocular microsaccades were recorded. Emmetropes modulate peak velocity and magnitude as a function of the level of blur imposed, obtaining larger peak velocities and magnitudes than myopes when experiencing both myopic and accommodation inducing blur. This was seen across all three target stimuli, each stimulus possessing different ranges of spatial frequency content. Natural image and Letter E targets shown larger differences between emmetropes and myopes than the Maltesse Cross target. Microsaccade frequency was a 20% higher on average in myopes than emmetropes (23.15 % LE, 21.74% MC, and 15.83% NI) .
Conclusions: Through the presented data, we provide initial evidence on the characteristics of microsaccades in myopes and emmetropic/hyperopic subjects for different levels of blur and frequency contents in the target.

TITLE: Efficacy of various glaucoma drop adherence techniques on glaucoma medication compliance

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Nagri, P. Janardhana, UMass Memorial Health, Worcester, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Shreya Nagri: Commercial Relationship: Code N (No Commercial Relationship) | Priya Janardhana: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The most common barriers to patient compliance in glaucoma treatment are lack of self-confidence in patients in administering medicine properly and difficulty of drop administration. This prospective survey study will compare different techniques to increase compliance by increasing patient confidence and competency in administering their glaucoma medications. The techniques that will be tested here are giving a glaucoma dropper-aid device vs showing an instructional glaucoma drop administration video.

Methods: In this study, we will conduct a pre and post-survey of glaucoma adherence questions, using the Morisky Medication Adherence Scale (MMAS-8) and the Quality of Life and Glaucoma 17-item questionnaire (GlauQoL-17). We grouped these individuals into either a control group with no intervention, a group given a glaucoma drop applicator with instructions on proper use, or another group showing a patient-provider education video on how to administer the drops properly at the clinic visit.

Patients will be given a post-glaucoma adherence survey questionnaire/satisfaction questionnaire 4 weeks post-intervention. Included are patients who are actively being treated for Primary Open Angle Glaucoma (POAG) at the UMass Memorial Eye clinic. Non-English speaking patients will be included only if their primary language is either Spanish or Portuguese because instructional videos were only provided in English, Spanish, and Portuguese.

Exclusion criteria include the following:

- Individuals <18 years old
- Prisoners
- Adults unable to provide consent (adults lacking consent, nonverbal)
- Non-English speaking patients, besides Spanish and Portuguese
- First-time glaucoma drop users

Our target recruitment is 50 participants.

Outcomes:

1. Improvement in medication compliance based on patient responses to Morisky Medication Adherence Scale and the Quality of Life and Glaucoma 17-item questionnaire

Results: Preliminary results are implying that patients who received video instruction or dropper-aid had an increase in adherence to glaucoma drops.

Conclusions: We hope to show that intervention with technology such as dropper-aids or video instruction, helps increase patient compliance with glaucoma drop treatment. With limited physician-patient interactions, it is important to understand what the optimal tools are that will help patients increase medication compliance.

TITLE: Cataract surgery outcomes in patients with amblyopia

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.S. Wijesingha, Bedford Hospital NHS Trust, Bedford, Bedford, UNITED KINGDOM|A. Sharma, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|J. Bradbury, West Suffolk NHS Foundation Trust, Bury Saint Edmunds, Suffolk, UNITED KINGDOM|S. Balal, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Naomi Wijesingha: Commercial Relationship: Code N (No Commercial Relationship) | Jack Bradbury: Commercial Relationship: Code N (No Commercial Relationship) | Shafi Balal: Commercial Relationship: Code N (No Commercial Relationship) | Anant Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cataract surgery associated with amblyopia can be challenging as there is an increased risk of operative complications and postoperative refractive surprise (as amblyopic eyes may be smaller or larger than other eyes), uncertain visual potential in the amblyopic eye and there is a risk of postoperative diplopia reported in the literature. Several factors may contribute to fixation switch diplopia, including surgical eye sequence, delay between surgeries and target refraction. The aim of this study was to review one year of cataract surgery in amblyopic patients at Moorfields Eye Hospital, Bedford, to assess visual potential and complications in this patient group.

Methods: Data from 42 consecutive patients who underwent bilateral phacoemulsification with known amblyopia was extracted retrospectively for cases between March 2018 and March 2019 with target refraction of emmetropia for both eyes. Parameters analysed included: preoperative and postoperative refractive status, preoperative and postoperative visual acuity (logMAR, best corrected and pinhole), presence/absence of diplopia, type of amblyopia (anisometropic, strabismic, visual deprivation), need for extra intervention/surgery, interval between surgery to fellow eye and eye sequence (dominant vs non-dominant first).

Results: The amblyopic eye was operated on first in 72% of cases, and no cases of postoperative diplopia were identified.

Conclusions: This study found no evidence for an increased risk of diplopia postoperatively. Visual acuity in the amblyopic eye can improve considerably after cataract surgery which is often delayed leading to an increased risk of complications associated with dense cataract. Operating earlier would relieve symptoms such as blur and avoid potentially difficult surgery.

ABSTRACT BODY:

Purpose: Bronchopulmonary Dysplasia (BPD) is the leading cause of serious pulmonary morbidity in premature infants. Recent work has found that retinal fundus photos (RFPs) can contain information relevant to systemic health in adults. In this study, we evaluated the hypothesis that RFPs obtained as part of ROP screening may predict a future diagnosis of BPD.

Methods: 5255 RFPs were collected from 871 patients as part of a multi-institutional Imaging and Informatics in Retinopathy of Prematurity (i-ROP) study. Apart from clinical information, the dataset comprised of Reference Standard diagnoses for Plus disease for all patients. All RFPs corresponding to either patients without a diagnosis of BPD or captured at PMA>=34 weeks were removed (since BPD is diagnosed at 36 weeks PMA), leaving 477 patients /1284 RFPs (Post Menstrual Age [PMA]- mean:32.43, std:0.88), which were then divided into Train, Val, and TestSets via 80:10:10 splits on patient level. A Deep Learning (DL) model was trained to predict BPD at 36 weeks using the TrainSet (1006 RFPs; BPD:429, Normal:577; Plus:13, Pre-Plus:23, Normal:970; [PMA]- mean:32.48, std:0.89). The best performing model with the highest AUC-ROC score on the ValSet (137 RFPs; BPD:61, Normal:76) was finally evaluated on the TestSet (141 RFPs; BPD:47, Normal:94; Plus:4, Pre-Plus:4, Normal:133; [PMA]- mean:32.27, std:0.74). To avoid the DL model learning any common biomarkers with ROP disease, a secondary model was trained with only Non- Plus/Pre-Plus images using a pruned TrainSet (970 RFPs; BPD:403, Normal:567; Plus:0, Pre-Plus:0, Normal:970; [PMA]- mean:32.47, std:0.89) and ValSet (127 RFPs; BPD:55, Normal:72), though the performance was reported on the original TestSet.

Results: The model trained with original TrainSet, performs with an overall AUC-ROC of 0.82 (image-level) and 0.86 (patient-level) on the TestSet (Fig.1). Performance improves to 0.84 (image-level) and 0.87 (patient-level) when the model is trained on a pruned TrainSet with only Non- Plus/Pre-plus images (Fig.2).

Conclusions: We found that a DL model trained on RFPs could predict a future diagnosis of BPD, even in babies with no clinical signs of ROP. In other words, the model isn't just learning that BPD and ROP often occur in the same babies. Early identification of babies at high risk for BPD may facilitate interventional trials to reduce morbidity from

BPD in the future.

ABSTRACT BODY:

Purpose: Pseudoexfoliation syndrome (PEX) is a systemic, age-related disorder characterized by the deposition of fibrillar material in body tissues. Pseudoexfoliation glaucoma (PEXG), the ocular manifestation of PEX, is the most common identifiable secondary form of open angle glaucoma. PEXG is characterized by greater IOP elevation, advanced loss of visual field upon diagnosis, and resistance to IOP therapies. Polymorphisms in lysyl oxidase-like 1 (LOXL1), an enzyme that crosslinks collagen/elastin and is critical for ECM formation and repair, significantly associates with PEX. Since LOXL1 levels appear lower and elastosis higher in people with PEX, the aim of the study was to characterize the ocular and non-ocular elastosis phenotypes associated with Loxl1$^{-/-}$ mice

Methods: 129S.C57Bl/6 Loxl1$^{+/-}$ mice were backcrossed onto C57Bl/6 or 129S background and aged for 2 months. Early onset and high prevalence of spontaneous anal prolapse in C57Bl/6 background mice necessitated the study of younger animals. Skin elastic recovery measurements, histology and western blots were performed to analyze systemic organ changes. For ocular studies, outflow facility was measured by iPerfusion, Schlemm's canal (SC) perimeter was quantified using ImageJ in semi thin histology sections, and the presence of extracellular matrix accumulation below inner wall of SC was documented by transmission electron microscopy

Results: Skin elastic recovery was significantly lower in Loxl1$^{-/-}$ N6 C57Bl/6 mice (23.18%) compared to Loxl1$^{-/-}$ from 129S.C57Bl/6 mice (48.67%) (p=0.0015). N6 C57Bl/6 Loxl1$^{-/-}$ mice showed qualitatively enlarged luminal spaces of lung and lax elastin orientation in both systemic and in ocular tissues. Densitometric analysis of western blots from lung tissue displayed increased tropoelastin expression in Loxl1$^{-/-}$ respect to Loxl1$^{+/+}$ for N6 C57Bl/6 mice (1.56-fold) and for 129S.C57Bl/6 mice (1.50-fold) ($p<0.05$). No changes were observed in outflow facility for both mice backgrounds, except between Loxl1$^{+/-}$ and Loxl1$^{-/-}$ (2.54 vs 4.48 nl/min/ mmHg) for the mixed background (p= 0.042). By TEM we observed increased ECM accumulation in the SC inner wall in Loxl1$^{+/-}$ and Loxl1$^{-/-}$ mice from both backgrounds

Conclusions: Results show that genetic background significantly influences the elastosis phenotype at both the systemic and ocular levels, providing an opportunity to identify the genes associated with genetic susceptibility

TITLE: Mitochondrial ROS in Slc4a11 KO corneal endothelial cells lead to ER stress

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Shyam, D.G. Ogando, J.A. Bonanno, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Raji Shyam: Commercial Relationship: Code N (No Commercial Relationship) | Diego Ogando: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Bonanno: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent studies from Slc4a11$^{-/-}$ mice have identified glutamine-induced mitochondrial dysfunction[BJA1] as a significant contributor toward oxidative stress, impaired lysosomal function, aberrant autophagy, and cell death in this Congenital Hereditary Endothelial Dystrophy (CHED) model. Because lysosomes are derived from the endoplasmic reticulum (ER) – Golgi, we asked whether ER function is affected by the lack of Slc4a11.

Methods: All experiments were conducted in 8 week old Slc4a11 WT and KO mice or in immortalized mouse WT and KO cell lines. Protein expressions were determined using the Simple Protein Wes® system. Real Time PCR analysis was conducted to amplify the transcripts of XBP1, unspliced-XBP1, spliced-XBP1, and β-actin. Fura-2AM was used to measure cytosolic calcium levels, and aggresomes were measured using a Proteostat Aggresome detection kit. In order to quench mitochondrial ROS, cells were treated with 2μM MitoQ for 16 hours.

Results: In mouse Slc4a11$^{-/-}$ corneal endothelial tissue, we observed the presence of dilated ER and elevated expression of ER stress markers BIP and CHOP. Slc4a11 KO mouse corneal endothelial cells incubated with glutamine showed increased aggresome formation, BIP, and GADD, as well as less ER Ca^{2+} release as compared to WT. Treatment of Slc4a11 KO cells with the mitochondrial ROS quencher MitoQ restored ER Ca^{2+} release and relieved ER stress markers indicating that mitochondrial ROS induces ER stress in corneal endothelial cells.

Conclusions: This study shows that in the presence of glutamine (in vivo or in vitro) the loss of Slc4a11 leads to ER stress that can be reversed by quenching mitochondrial ROS. Mitochondrial ROS also triggers lysosomal dysfunction with autophagy impairment in Slc4a11$^{-/-}$ corneal endothelial cells. Since lysosomes are derived from ER-Golgi, our findings suggest that ROS-induced ER stress is an important trigger for cellular dysfunction in the Slc4a11 KO model.

TITLE: Genetic dissection of the delivery pathways for vitamin A to ocular tissues in mice

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Moon, R. Srinivasagan, J. von Lintig, Pharmacology, Case Western Reserve University School of Medicine, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Jean Moon: Commercial Relationship: Code N (No Commercial Relationship) | Ramkumar Srinivasagan: Commercial Relationship: Code N (No Commercial Relationship) | Johannes von Lintig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The eyes acquire vitamin A derived from either the extrinsic or intrinsic pathway, distributing vitamin A from intestinal enterocytes or from hepatic stores. Vitamin A deficiency or excess are commonly associated with blinding and inflammatory diseases. However, we have a limited understanding of mechanisms controlling the distribution pathways. We used a genetic dissection approach in transgenic mice to investigate how ocular homeostasis is perturbed under different dietary supply conditions.

Methods: We utilized mice with mutations in intestine-specific transcription factor (ISX) or stimulated by retinoic acid gene 6 (STRA6) which have been identified as gatekeepers of the extrinsic and intrinsic pathways, respectively. Mice were supplemented with preformed vitamin A (4,000 IU/kg) or β-carotene (25 mg/kg) for 7 wks. Scotopic and photopic responses were then recorded from mice that were dark adapted overnight using ERG. Retinoid concentrations were measured by HPLC, and retinoid-dependent processes were evaluated by gene and protein expression analyses. Rhodopsin and M-opsin levels were evaluated by immunohistochemistry in retinal cross sections and whole mounts.

Results: We observed $Isx^{-/-}$ mice possessed normal ocular vitamin A concentrations but acquired high levels of retinoids in peripheral tissues in a STRA6-dependent manner. Ocular retinoid levels were significantly lower in $Stra6^{-/-}$ compared to WT and $Isx^{-/-}$ mice. $Stra6^{-/-}$ mice displayed significant reduced photopic responses and M-opsin staining. Interestingly, genetic deletion of ISX partially rescued ocular vitamin A deficiency in $Isx^{-/-}$/$Stra6^{-/-}$ mice. Remarkably, photopic ERG responses were significantly improved in $Isx^{-/-}$/$Stra6^{-/-}$ double-knockout mice compared to that of the $Stra6^{-/-}$ counterparts. The double-knockout mice displayed a significant recovery of cone photoreceptors. However, the rescue of vision came at the expense of a massive accumulation of vitamin A in other tissues, demonstrating that vitamin A is randomly distributed when present in excessive amounts.

Conclusions: Our analysis in different genotypes revealed STRA6 is critical for maintaining ocular vitamin A homeostasis and cone photoreceptor function. The partial rescue of vision in $Isx^{-/-}$/$Stra6^{-/-}$ double-knockout mice was associated with hyper-vitaminosis A in most peripheral tissues, demonstrating the requirement of an eye-specific delivery pathway of the essential nutrient.

Commercial Relationships Disclosure: Binapani Mahaling: Commercial Relationship: Code N (No Commercial Relationship) | Rajiv Mohan: Commercial Relationship: Code N (No Commercial Relationship) | Shyam Chaurasia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sulfur mustard is a chemical weapon threat, and its exposure to the eye causes severe eye pain, photophobia, excessive lacrimation, anterior segment defects and blindness. This study aims to evaluate the possible effects of mustard gas toxicity on retinal Muller glial cells.

Methods: Muller glial cells (MIO-M1) were cultured in DMEM and exposed to nitrogen mustard at different concentrations (50-1000μM) for 3h, 24h and 72h. Real-time cellular integrity and morphological evaluation were done using the xCELLigence system. Cellular toxicity and viability were performed using TUNEL and Prestoblue assays. The intracellular oxidative stress was measured by DCFDA, and DHE staining and antioxidant gene expression was determined by qPCR. The effect of nitrogen mustard on glial cell activation was determined by GFAP and vimentin antibody staining and by qPCR of inflammatory markers. AO/PI and DAPI staining further evaluated cell death, apoptosis, necrosis, and DNA damage. We assessed the pyroptosis mechanism by measuring caspase-1, caspase-3, and ASC and NLRP3 inflammasome using immunoassays.

Results: The cellular and morphological evaluation revealed hyperactivation of Muller glial cells after nitrogen mustard exposure in a dose- and time-dependent manner. Nitrogen mustard significantly increased oxidative stress up to 24h with enhanced cell death in 72 h. We found a significant increase in antioxidant enzymes at lower concentrations of nitrogen mustard. Increased oxidative stress and inflammatory milieu caused activation of NLRP3 inflammsome resulting in Muller cell gliosis. NM-induced cell death was mainly driven by caspase-1 and NLRP-3 pyroptosis and was less dependent on caspase-3.

Conclusions: In conclusion, the nitrogen mustard caused retinal Muller glial cell gliosis with increased oxidative stress, inflammation, and cell death primarily driven by caspase-1/NLRP3 pyroptosis.

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is a leading cause of vision loss in patients with diabetes mellitus. Current treatment for DME requires frequent intravitreal injections, resulting in a significant burden on patients. Nondamaging focal laser is a newer therapy designed to treat DME without permanently damaging the retina. This study aims to assess the impact of adjunctive laser therapy on the injection burden and on visual acuity in patients with DME.

Methods: A retrospective analysis of 18 eyes of 14 patients with DME treated with the Pascal 532nm Endpoint Management (Synthesis Photocoagulator, Iridex, USA) was conducted. Demographic data, visual acuity, laser treatment parameters, and anti-VEGF injection burden six months before and after treatment were collected. Wilcoxon Signed-rank tests were used to assess changes in visual acuity and injection burden before and after treatment.

Results: Eighteen eyes of 14 patients were included in this study. Mean age at time of treatment was 62.6 +/- 17.1 years. Twelve patients had type 2 diabetes and two had type 1 diabetes. Eight patients had proliferative diabetic retinopathy, two had mild non-proliferative diabetic retinopathy (NPDR), two had moderate NPDR, and two had severe NPDR. All patients were followed for a minimum of six months following the laser treatment. All patients were treated with 30% of threshold laser with landmarks off and laser spot size of 200 micrometers, pulse duration of 15 milliseconds, and spacing of 0.25 Φ apart. Mean number of spots was 655.6 +/- 160.5. Mean number of intravitreal injections in the six-month period prior to laser treatment was 3.39+/- 2.57 injections compared to 2.33 +/- 2.40 injections in the six months following laser treatment (p=0.02). There was no significant difference between mean visual acuity on the day of treatment compared to visual acuity on the most recent follow-up (p=0.34), logMAR VA of 0.38 +/- 0.27 (approx. Snellen equivalent 20/50) and logMAR VA of 0.35 +/- 0.32 (approx. Snellen equivalent 20/40), respectively.

Conclusions: Subthreshold focal retinal laser therapy is associated with a statistically and clinically significant decrease in the number of intravitreal injections required in the six-month period immediately following treatment, without compromising visual acuity. This laser has the potential to alleviate the burden of injections on both patients and clinics.

Hambleton, Biostatistics, The University of the West Indies at Cave Hill, Bridgetown, Saint Michael, BARBADOS|

ABSTRACT BODY:

Purpose: This study describes the patterns and causes of visual impairment in Barbadian children.

Methods: A retrospective chart review of all patients 18 years and younger who presented to the sole public pediatric ophthalmology clinics in Barbados at Queen Elizabeth Hospital (QEH) and Winston Scott Polyclinic (WSPC) between Jan 1st and Dec 31st, 2019 was conducted. Age at the first visit to an eye care provider (A_0) and final visit in 2019, sex, visual acuity and clinical diagnoses were obtained and stored using a REDCap data collection tool.

Results: 955 patient charts were collected from QEH (Jul to Dec) and WSPC (Nov to Dec) with a male: female ratio of 1:1. 11.5% of patients met the WHO criteria for visual impairment (4.5% binocular and 7.0% monocular), with an A_0 of 4.0 years. Refractive error (59.4%) and strabismus (36.9%) were the most common diagnoses among this group (Fig. 1), of which 79.4% had amblyopia. Overall, refractive error was the most common ocular disorder seen in the study population (39.6%), followed by allergic eye disease (35.2%), and strabismus (14%). Children aged 5 to 11 years old comprised the largest group of patients seen in 2019 with an A_0 of 5.9 years.

Conclusions: The burden of eye disease in the Barbadian adult population was described in the Barbados Eye Study over 20 years ago. However, no such studies have been conducted on the pediatric population. Causes of visual impairment in the Barbadian population are treatable and preventable. This preliminary data revealed that refractive error and strabismus were the leading causes of visual impairment in children. These results are comparable with trends observed in epidemiological studies conducted in the United States. On average, Barbadian children are first seen by an eye care provider when they are almost 6 years old. This is later than the US Preventative Services Task Force's recommended age for pre-school vision screening of 3-5 years. The causes of visual impairment observed in this study can be detected and treated with earlier vision screening. This study only reflects those children whose caregivers actively sought ophthalmic attention through the public sector. Implementation of a nation-wide vision screening program can identify children who do not receive eye care and improvements can be made in the approach to pediatric eye disease in Barbados.

ABSTRACT BODY:

Purpose: Mechanisms underlying abnormal choriocapillaris vascular changes, seen in wet age-related macular degeneration, are unknown. Nuclear receptors (NR) are a family of transcription factors responsible for various cellular homeostatic mechanisms and vascular changes during development/disease. We created a NR atlas of human choroidal endothelial cells (CEC), freshly isolated choroid (FI), and choroid from a wet AMD mouse model, to identify candidate receptors that may play a role in vascular stability and/or disease.

Methods: Samples: (a) CECs isolated from human donor eyes (n=6 males and 2 females, ages 47-90, normal ophthalmic history), through positive enrichment by VE-cadherin cell sorting; b) FI human choroid (n=3 males and 3 females, ages 61-90) and (c) choroid from aged laser induced CNV and control C57BL/6J mice (n=2-3 females and 11 males/cohort). CECs were plated on gelatin/fibronectin til confluence, dissociated, and sorted with a CD31 antibody to ensure a pure cell population. RNA was isolated (n=3 passages up to passage 5), integrity evaluated with an Agilent Bioanalyzer, and cDNA synthesized. Expression of all 48 NRs plus the aryl-hydrocarbon receptor (AhR) and AhR translocator (ARNT), in human CECs and FI, were determined by relative absolute qRT-PCR (arbitrary expression ratio=arbitrary mass of housekeeping gene/NR±SEM) and by PCR array for mouse samples.

Results: The highest expressed NRs came from the thyroid hormone receptor-like subfamily [LXRβ (CEC: 1.22±0.02; FI: 1.04±0.02), PPARβ/δ1 (CEC: 1.01±0.02; FI: 1.02±0.05), PPARβ/δ2 (FI: 1.09±0.08), RARα (CEC: 1.03±0.04; FI: 1.15±0.05), RARβ (CEC: 1.47±0.05; FI: 1.80±0.12), RARγ (CEC: 1.34±0.07; FI: 1.15±0.05), Rev-ErbAβ (CEC: 1.14±0.03; FI: 1.04±0.07), RORα (FI: 1.15±0.04), RORβ (FI: 1.15±0.06), and RORγ (FI: 1.15±0.06)]. Highly expressed RXR-like NRs included RXRγ (FI: 1.44±0.04), COUP-TFII (CEC: 1.02±0.02), V-erbA-related (CEC: 1.17±0.03), and TR4 (CEC: 1.01±0.01; FI: 1.10±0.05). AhR (CEC: 1.41±0.04; FI: 1.33±0.12) and ARNT (FI: 1.00±0.02) were also highly expressed. Remaining NRs were categorized into intermediate (CEC, n=12 NRs; FI, n=10 NRs), low (CEC, n=13 NRs; FI, n=17 NRs), and absent (CEC, n=15 NRs; FI, n=12 NRs) expression bins.

Conclusions: With this atlas we identified candidate receptors (e.g. LXR, AHR, RARα, RARβ, RARγ, COUP-TFII, REV-ERBAα, REV-ERBAβ, PPARβ/δ1, PPARβ/δ2, RORα, and RXRγ) as potential regulators in vasculature homeostasis/disease.

ABSTRACT BODY:

Purpose: To evaluate the effect of contrastive learning (CL)-based pre-training on the performance of diabetic retinopathy (DR) classification

Methods: We have developed a CL-based method to produce models with better representations and initializations for the detection of DR in color fundus images. Our model takes in image data, uses two-step data augmentation (neural style transfer + random geometric augmentation) to create a pair of augmented images, and then uses contrastive loss to maximize similarity of the two images in encoded space. The contrastive learning framework contains a Resnet50 encoder (CNN, ReLU, maxpool, and dense layers) with a projection head that maps the representation. The CL training utilizes a high batch size of 2048 and is trained for 100 epochs. Once the model is trained, the encoder(Resnet50) is used as a pre-trained model for a DR classification task (non-referrable vs referable DR). We compare our model with a model pre-trained with Imagenet weights. The model is trained and validated on a Kaggle dataset (35,126 fundus data) with 10–fold cross validation (split as training and validation set) and tested independently on real-life data (2,500 fundus data) from the University of Illinois (UI) Retina Clinic. For the DR classification, a learning rate of 1e-5 with gradual decay, batch size of 64, dropout rate of 0.4, and ADAM optimizer are used as hyperparameters

Results: The CL trained model performed significantly better compared to the Imagenet trained model (AUC of 0.94(CI 0.90-0.99, $p<0.001$) vs 0.82(0.75-0.85, $p<0.001$) on Kaggle data and 0.91(0.88-0.96, $p<0.001$) vs 0.8(0.74-0.85, $p<0.001$) on UI data). We reduced the training data size to 10% of the total data. At 10% training data, the AUC was 0.84(0.8-0.87, $p<0.05$) for CL model vs 0.69(0.59-0.75, $p<0.05$) on Imagenet model (Kaggle data) and 0.81(0.79-0.86, $p<0.05$) vs 0.65(0.6-0.75, $p<0.05$) for UI data. The results reflect that the model generalized well(transferable from Kaggle to UI data) and CL based training allowed to utilize a small number of annotated data(10%) while still generating good diagnostic accuracy

Conclusions: CL based pre-training with neural style transfer significantly improves DL classification performance and allows training with small, annotated datasets,therefore reducing ground truth annotation burden of the clinicians

TITLE: Role of the vitreous in ocular biomechanics
SESSION TITLE: Novel animal models and neuroprotection in the retina
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: J. Marques, P. Baptista, J. Coelho, M. Menéres, A. Meireles, J. Melo Beirão, Centro Hospitalar Universitario do Porto EPE, Porto, PORTUGAL|
Commercial Relationships Disclosure: João Heitor Marques: Commercial Relationship: Code N (No Commercial Relationship) | Pedro Manuel Baptista: Commercial Relationship: Code N (No Commercial Relationship) | João Miguel Coelho: Commercial Relationship: Code N (No Commercial Relationship) | Maria João Menéres: Commercial Relationship: Code N (No Commercial Relationship) | Angelina Meireles: Commercial Relationship: Code N (No Commercial Relationship) | João Melo Beirão: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:
Purpose: To analyze, for the first time in vivo, the role of the vitreous in ocular biomechanics.
Methods: Prospective longitudinal study that included 24 patients submitted to unilateral pars plana vitrectomy (PPV) for vitreous opacities or epiretinal membrane. Ocular biomechanics were analyzed with Oculus Corvis ST one week before and one month after surgery. The whole eye movement (WEM) was analyzed separately as a function of posterior segment compression. Posterior vitreous detachment (PVD) was access optical coherence tomography. The fellow non-operated eyes were used as control
Results: After PPV, we observed changes in biomechanics towards a softer corneal behavior, namely a reduction in SP-A1 (p=0.009). However, intraocular pressure (IOP) was also lower (p=0.034). WEM distance decreased after vitrectomy (p=0.020). There were no significant differences in fellow non-operated eyes. A cross-sectional comparison before PPV showed that eyes with PVD at the macula also have a shorter WEM distance (p=0.047). There were no significant differences according to the reason for PPV (vitreous opacities in 16 eyes or epiretinal membrane in 8 eyes).
Conclusions: This study shows changes in response to an air pulse after PPV, which suggest a role of the vitreous in ocular biomechanics. Due to the lower IOP after surgery, no definite conclusions may be drawn regarding corneal measurements and indexes. More importantly, we observed changes that relate to the posterior segment of the eye, namely the vitreous. A decrease in WEM distance conveys a reduction in anterior-posterior deflection and reduced compression of the posterior segment. Lower IOP alone would produce the opposite effect. Eyes with PVD may also have reduced WEM. Together these findings demonstrate, for the first time in vivo, that the attached vitreous exerts a centripetal force on the globe.

ABSTRACT BODY:

Purpose: Retinal ischemia is a major cause of vision loss in a number of degenerative retinal diseases, including diabetic retinopathy (DR). The up-regulation of heme oxygenase (HO-1) has shown to be protective. The precise mechanism(s) by which HO-1 confers protection against cellular stress and tissue injury has not been defined, however, overwhelming evidence in the literature points to carbon monoxide (CO) generation. Low doses of CO have shown the potential for benefit in numerous disease paradigms. The impact of low dose CO therapy on conditions of the retina has not been widely evaluated. HBI-002 is an oral drug product containing precise amounts of CO. In the present study, we evaluated the therapeutic efficacy of HBI-002 in regulating retinal ischemia-reperfusion (I/R) in mice.

Methods: Male C57BL/6J mice (8-10 weeks old) were anesthetized and subjected to retinal ischemia by inserting a 32-gauge needle in the anterior chamber of the right eye to infuse sterile saline. The intraocular pressure was raised to 110 mm Hg and maintained for 40 min, after which reperfusion was begun by removing the needle. HBI-002 or vehicle (2 mg/kg) was orally administered to mice 60 minutes before I/R and then dosed daily for 7, 14, or 28 days with two doses of 2 mg/kg 60 min apart. Endpoint analyses included optokinetic tracking and electroretinogram (ERG) analysis as well as monitoring for changes in oxidative stress, inflammation, morphometric changes, and neurodegeneration by immunohistochemistry and Western blotting analysis.

Results: Oral treatment with HBI-002 significantly induced HO-1 expression thereby inducing a significant antioxidant response in the retinas of HBI-002 treated mice. The thickness of the total retina and of the inner nuclear layer was preserved as were ganglion cells in I/R-injured eyes of HBI-002 treated mice. Importantly, visual function was significantly better as evidenced by increases in spatial frequency threshold and improved ERG responses in I/R-injured eyes in HBI-002 treated mice.

Conclusions: Collectively, our proof-of-concept studies provide significant evidence for the therapeutic potential of HBI-002 in improving retinal I/R injury in mice. HBI-002 will enter Phase I testing in healthy subjects in early 2022, and rapid clinical evaluation in retinal disease could follow.

TITLE: Optic Nerve-Independent Light Perception in Mouse Models of Photoallodynia

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Matynia, S. Parikh, M.B. Gorin, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|A. Matynia, S. Parikh, J. Suwanwanitch, M.B. Gorin, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Anna Matynia: Commercial Relationship: Code N (No Commercial Relationship) | Sachin Parikh: Commercial Relationship: Code N (No Commercial Relationship) | Jade Suwanwanitch: Commercial Relationship: Code N (No Commercial Relationship) | Michael Gorin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Light mediates reflexive behavior via optic nerve pathways such as the pupillary light reflex and trigeminal pathways such as the photic corneal blink reflex. Photoallodynia is a painful response induced or enhanced by light, common to many distinct ocular conditions from cone-dominant dystrophies to corneal injury to migraine. The contributions of the optic and trigeminal nerves to light and pain perception using light aversion, a surrogate for photoallodynia, was investigated.

Methods: Light aversion behavior at 1000 lux was quantitated as an aversion index (AI: 0=no aversion; 1=complete aversion) in wild type (WT) mice and mice lacking rod and cone photoreceptors (Usher 1B, USH), in combination with optic nerve lesions (Optic Nerve Only – ONO, Trigeminal and Optic nerve, Artery and Sheath Transection – TOAST) or bilateral enucleation (BiLat). Nitroglycerin (NTG), a model for migraine, and morphine (MOR) were used to unmask light aversion. Acoustic startle was used to evaluate drug-induced acoustic hypersensitivity. Immunohistochemistry was used to evaluate retinal ganglion cells.

Results: All mice with surgical lesions or enucleation exhibited minimal-to-no light aversion with vehicle. NTG-induced and MOR-induced light aversion in wild-type mice was highest in sham (NTG=0.81±0.06, n=12; MOR=0.88±0.06, n=14), and reduced after ONO (NTG=0.51±0.09, n=13; MOR=0.12±0.06, n=13), TOAST (NTG =0.22±0.13, n=8; MOR=0.63±0.13, n=8) and BiLat (NTG =0.01±0.04, n=6; MOR=0.55±0.12, n=6). USH mice have intact melanopsin-expressing retinal ganglion cells and normal drug-induced light aversion (NTG =0.87±0.04, n=20; MOR=0.78±0.06, n=20) that is significantly reduced after BiLat (NTG =0.25±0.08, n=10; MOR=0.22±0.09, n=10). NTG and MOR do not affect acoustic startle responses.

Conclusions: Retinal-optic nerve pathways mediate light aversion in disease- and injury-free states. Trigeminal pathways are recruited in pathophysiological states and may represent a major component that signals light-induced or -enhanced pain. Acoustic stimuli do not further enhance light aversion, indicating distinct pathways from acoustic blink reflexes. NTG and MOR provide useful tools for identifying the neural circuit(s) underlying this latent light perception. Melanopsin expression has been observed in trigeminal ganglion neurons that respond to light ex vivo, providing a potential alternative circuit to influence light aversion.

ABSTRACT BODY:

Purpose: Damage to the corneal sensory nerve endings contributes to the emergence of refractory pain in neuropathic corneal pain (NCP), for which there are currently no approved therapies available. Proenkephalin-derived endogenous peptide, BAM8-22, has been attributed with generating analgesia. In this study, we evaluated the effect of topical ophthalmic therapy with BAM8-22 peptide analogues on NCP, in a murine model of ciliary nerve ligation.

Methods: Eye-wipe response to topical hyperosmolar saline (HOS) was used as the primary outcome measure. Following the establishment of a baseline eye-wipe response to HOS [5M], 10–12 week-old male mice underwent ciliary nerve ligation for induction of NCP. Post-surgery, corneal fluorescein staining (CFS) and Cochet-Bonnet esthesiometry were used to assess ocular epithelial integrity and corneal sensitivity in operated mice that had a positive corneal pain outcome. Animals were randomized in treatment groups (n=5) and topically treated with lipidated BAM8-22, non-lipidated BAM8-22, and vehicle for 11 days. Systemic gabapentin was used as the positive control. Excised corneal whole mounts were immunostained for ßIII-Tubulin and CD45 to assess nerve and immune cell density alterations.

Results: NCP induction surgery generated a sustained pain response in all mice (24.46±1.32 vs.12.62±1.25 eye wipes/30 sec, $p<0.05$). Corneal sensitivity amongst all the treatment groups remained intact and no corneal epithelial defects were observed post-surgery. Topical application of both lipidated BAM8-22 analogue (24.2±1.59 vs.12.6±0.98, $p=0.045$) and non-lipidated BAM8-22 (25.17±1.66 vs.13.18±0.7, $p=0.018$) resulted in a decrease in pain response compared to vehicle treatment. Systemic gabapentin treated mice were used as the positive control and showed a lowered pain response (25.5±2.25 vs.12.5±2.6, $p=0.011$). Corneal nerve density decreased in all the NCP mice compared to sham (64884.53±4353.51 vs. 152348.87±6344.17 mm/mm^2, $p<0.0001$). Among all the different NCP treatment groups, significantly higher corneal nerve density was detected in non-lipidated BAM8-22 treated mice as compared to vehicle (104188.79±5622.31 vs. 54429.42±6343.29 mm/mm^2, $p<0.0001$) while no significant differences were observed in the $CD45^+$ cell density among groups ($P>0.05$).

Conclusions: BAM8-22 analogues, administered topically, were effective in alleviating neuropathic corneal pain in our murine model of NCP.

TITLE: A mathematical model to understand the formation of the outer retinal corrugations

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Norouzi Darabad, A. Ramachandran, Department of Chemical Engineering and Applied Chemistry, University of Toronto, Toronto, Ontario, CANADA|P. Oquendo, H. Hamli, W. Lee, F. Nagel, A. Bansal, I.M. Melo, R.H. Muni, Department of Ophthalmology and Vision Sciences, University of Toronto, Toronto, Ontario, CANADA|

ABSTRACT BODY:

Purpose: Outer retinal corrugations (ORCs) can often result in outer retinal folds (ORFs) and poor vision in patients with rhegmatogenous retinal detachment (RRD). However, the pathophysiology of ORCs is not well understood. We have developed a mathematical model to further understand the mechanical aspects of the formation of ORCs. In particular, we are interested in the changes in mechanical properties of the retina that result in the formation of ORCs.

Methods: We have modeled the retina as a composite material consisting of the outer retinal layer (photoreceptor layer) and the inner retinal layer (the part of the retina that excludes the photoreceptor layer) with thicknesses T_o and T_i and elastic modulus E_o and E_i respectively. We selected optical coherence tomography (OCT) images of 8 RRD patients with visible ORCs and no cystoid macular edema (CME). The thickness of the outer and inner retinal layers, and the relative increase in the length of the outer retinal layer (γ) is measured from OCT images. This information is used along with the mathematical model to find the values of E_o / E_i resulting in corrugations with frequency similar to OCT imaging.

Results: Measurements from OCT images of patients with RRD show that there is approximately 30% increase (γ=0.3) in the length of the outer retinal layer and a 400% increase in the thickness of the outer retinal layer (T_o). Using our mathematical model, we found that in order to form corrugations with a frequency similar to what is observed on OCT imaging E_o / E_i should be 0.1 or smaller. In other words the outer retinal layer should become 10 times softer compared to inner retinal layer. It is noteworthy that this trend is the opposite of that observed in an attached retina, i.e. the outer retina is stiffer than the inner retina. This indicates that the outer retina could be undergoing significant structural changes and softening relative to the inner retina when detached from the RPE.

Conclusions: We compared predictions from a mathematical model with measurements from OCT images to make inference about the mechanical conditions required for the formation of ORCs. Our results show that the outer retina should undergo structural changes that reduces the elastic modulus of the outer retinal layer such that $E_o / E_i \leq 0.1$. These results have significant implications on how best to achieve retinal reattachment to reduce abnormalities such as outer retinal folds.

ABSTRACT BODY:

Purpose: To investigate age-dependent changes in mouse retinal epithelium (RPE) cells, including cell number, cell size, and the concentration of the pigmented granules and their emission spectra, using multicolor confocal fluorescent microscopy (MCFM). These changes were compared between a mouse model of Stargardt disease ($Abca4^{-/-}$ [129S4]) and agouti wild-type (WT) controls.

Methods: We performed in situ live tissue imaging of RPE flat-mounts from agouti $Abca4^{-/-}$ and agouti WT (129S1/SvlmJ) controls at multiple ages (1.5 months, 4 months, 8 months and 13 months) using a Nikon A1 confocal microscope. High-resolution confocal image z-stacks of the RPE cell mosaic were acquired with four different excitation wavelengths (405nm, 488nm, 561nm, and 640nm). The autofluorescence images of RPE, including voxel-by-voxel emission spectra, were acquired and processed with Nikon NIS-AR Elements software.

Results: An enhanced visualization of the RPE cell mosaic as well as pigmented granules (melanosomes and lipofuscin) with an unprecedented resolution and contrast were generated using MCFM for both mouse strains at all ages. The changes in RPE cell number, cell volume, concentration of the lipofuscin and melanosomes (per cells), the emission spectra from the lipofuscin granules, and the total emission spectra from the RPE volume were quantified and compared over time between strains. We found the concentration of lipofuscin consistently increased with age whereas the number of melanosomes decreased proportionally in both mouse strains. At all ages there was an increased number of lipofuscin granules in $Abca4^{-/-}$ compared to WT.

Conclusions: A systematic and comprehensive investigation of the age-dependent changes in RPE cells and pigmented granules was possible with MCFM. An increased number of lipofuscin and decreased number of melanosomes with age is common in both mouse strain, albeit, more rapid in $Abca4^{-/-}$. The reduction in melanosomes could be linked with the formation of melanolipofuscin, which requires additional investigations. The changes in the RPE with age and $Abca4^{-/-}$ deficiency could be linked the pathological condition associated with a Stargardt disease.

ABSTRACT BODY:

Purpose: The ability to safely and reliably monitor visual function at home can help to facilitate the reduction of the personal, economic and environmental burdens of AMD through early identification of deterioration. A critical success factor is real-world patient acceptability and ease of use. Therefore, this study aimed to: 1) evaluate the clinical validity of the OKKO Health visual acuity data versus in clinic measures of visual acuity; and 2) explore the usability and acceptability of home vision monitoring.

Methods: Participants undergoing regular anti-VEGF injections in an NHS macular clinic were invited to participate. Patients were trained in the use of the OKKO Health app by the nurse practitioner and instructed to play three times weekly, between their scheduled monthly clinic visits. Participants were followed up for three months and a total of four clinic visits, during which chart LogMAR visual acuity was measured using a ETDRS eye chart. This was compared to the app visual acuity data in the week preceding the clinic appointment. Usability of the OKKO Health app was determined through the use of the system usability scale.

Results: Data presented are from a larger ongoing study. Of the 50 adults consented (Age range: 79 ± 7 years; range: 65 - 88), 72% (n = 36) initially downloaded and registered the app. Of these, 44% (n = 16) played consistently three times per week for three months. Bland-Altman analysis was carried out on a total of 60 sessions showing good agreement with the OKKO Health app. On average, the OKKO visual acuity score was 0.077 logMAR ± 0.23 logMAR better than in-clinic measurements using an ETDRS eye chart. The average score on the system usability scale was 83 ± 13, suggesting excellent usability in those who downloaded the app.

Conclusions: The OKKO Health app provides a feasible (usable and valid) means of monitoring visual function at home and was well-accepted with good adherence by patients who initially downloaded and registered on the app.

TITLE: Participatory Evaluation of Framework Outlining Barriers to and Facilitators of Diabetic Retinopathy Screening Utilization in a High-Risk Population

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Andoh, A. Norcott, K.H. Nwanyanwu, Ophthalmology and Visual Science, Yale School of Medicine, New Haven, Connecticut, UNITED STATES|E. Fairless, Ophthalmology, The University of Oklahoma, Norman, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure: Joana Andoh: Commercial Relationship: Code N (No Commercial Relationship) | Althea Norcott: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Fairless: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Nwanyanwu: Commercial Relationship(s);Code O (Owner):Eyefull, LLC

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of blindness in working-age people in the US. DR is more prevalent and diagnosed at more severe stages in racial and ethnic minorities and low resource communities. Our group developed a framework to organize determinants of DR screening in a high-risk population. The purpose of this study was to evaluate this framework to identify additional barriers to and facilitators of DR screening applicable to those with severe disease.

Methods: We conducted individual semi-structured, qualitative interviews of participants with a history of laser or surgery for DR at an urban, academic health center. We recorded select demographic information of each participant. After the interview, participants were compensated with a monetary gift card. Interviews were recorded, analyzed, and organized in comparison to the initial framework based on grounded theory. To conduct a participatory evaluation, we recruited and trained a community stakeholder to analyze four transcripts. The study authors discussed evaluation findings, synthesized poignant themes, and proposed interventions.

Results: A total of 28 participants were included in the final analysis. Four additional participants were required for the severe disease cohort to reach theoretical saturation. Eleven participants identified as female and 17 identified as male. Participants identified as Black (17), White (4), Hispanic/Latinx (4), and other/no answer (3). The original coding framework themes remained relevant (Figure 1). Themes were organized into two categories: individual (vision status, competing concerns, emotional context) and structural factors (resource availability, cues to action, knowledge-creating experiences, and in-clinic experience). The patient-doctor relationship was an additional theme present in the severe cohort analysis. During the participatory evaluation, the community stakeholder highlighted examples of select themes, in addition to possible interventions (Figure 2).

Conclusions: We present participatory evaluation as a means of reviewing a framework to identify barriers and facilitators to diabetic retinopathy screening in a high-risk population. The emergence of poignant themes and possible interventions emphasize the importance of participatory research in understanding social determinants of diabetic retinopathy.

ABSTRACT BODY:

Purpose: Inaccurate accommodation responses to blur may be associated with myopia. Conflicting results in previous studies may be a result of varied stimuli characteristics. We sought to compare static and dynamic accommodation responses (AR) and associated pupil constriction to two different stimuli in children.

Methods: Static and dynamic AR and pupil sizes were measured on the right eyes of young children (N=97, 7.58±0.96yrs) with functional emmetropia (SE OD +0.95±0.54D; AXL OD 22.79±0.75mm) using a WAM-5500 open-field binocular autorefractor WMT-2 Moving System (Ait, Luneau). Two targets of 'dead leaves' stimuli which capture spatial characteristics of natural images were used: the real object (3D), and a flat, 2D picture of the same object. Static AR were measured for a 2.5D demand. Dynamic AR were measured for a sinusoidally moving stimuli (27 seconds, 1-4D demand, 9 second-cycles) and results fitted with sinusoidal functions. Children were classified into High Risk (HR) or Low Risk (LR) for myopia based on their parental myopia and baseline refractive error.

Results: Static AR for a 2.5D demand did not differ significantly between the 2D (1.79±0.45D) and 3D (1.75±0.51D) stimuli ($p>0.05$). Pupil sizes were also not significantly different (2D: 5.89±0.89mm, 3D: 5.97±0.85mm; $p>0.05$). Children at LR for myopia accommodated significantly more accurately than those at HR when viewing both static 2D (LR: 1.89±0.48D, HR: 1.68±0.38D; $p=0.006$) and 3D stimuli (LR: 1.83±0.62D, HR: 1.65±0.34D; $p=0.007$). Dynamic accommodation amplitudes were larger for the 2D (1.27±0.21D) than the 3D (1.24±0.23D, $p=0.025$) stimuli, and latencies longer for the 3D stimuli (2D: 0.34±0.22msec, 3D: 0.42±0.28msec; $p=0.008$). AR amplitudes were significantly larger for children at LR compared to those at HR for myopia (2D - LR: 1.31±0.17D, HR: 1.22±0.19D; $p=0.037$; 3D - LR: 1.32±0.18D, HR: 1.15±0.23D; $p<0.001$) stimuli.

Conclusions: No overall differences were found between the 2D and 3D stimuli for static responses, but the dynamic amplitudes and latencies were more accurate with the 2D compared to the 3D stimuli. Children with LR for myopia showed more accurate static and dynamic responses than those at HR for myopia. Differences in AR in young children may predict the development of myopia.

Hofmann La Roche

ABSTRACT BODY:

Purpose: Calcium phosphate minerals are ubiquitous constituents of retinal drusen (PMID 25605911) and the presence of larger hydroxyapatite (HAP) deposits termed nodules is predictive of progression to advanced AMD within one year (odds ratio 6.4 : 1)(PMID 30404862). HAP can be imaged by fluorescence lifetime imaging microscope (FLIM) following staining with common tetracycline antibiotics (PMID 32319262). These results and others suggested that imaging HAP deposition in the retina might prove a useful biomarker for the early detection and monitoring progression of AMD and other diseases. However, some of the best performing tetracyclines are best excited at wavelengths near 400 nm, which raises safety issues and where background fluorescence particularly in the vitreous and lens is strongly excited. Since multiphoton excitation occurs only at the focal point, such imaging is effectively confocal and background fluorescence in the excitation path is minimized. In addition, there are minimal safety concerns with the excitation wavelength used by the two photon system (780 nm in this experiment) as it is similar to the wavelengths widely and safely used for OCT. Here we tested multiphoton excitation for imaging HAP in a FLIM using an ultrafast laser in the near-infrared for fluorescence excitation of HAP-bound tetracyclines.

Methods: Donors provided consent under ethical standards. Cadaver eyes were dissected, flat-mounted, and stained with chlortetracycline or solutions essentially as previously described (PMID 32319262) and imaged in an ISS Alba FLIM with excitation at 780 nm, 90 fsec pulse duration, and 12 mW average power through a 20 X 0.7 NA objective. The instrument was calibrated with standards of known lifetimes.

Results: Both HAP-bound doxycycline and chlortetracycline were efficiently excited by focused 780 nm pulses; measured average lifetime values were similar (3.6 and 1.9 nsec, respectively) to those measured previously for HAP-bound tetracyclines with one photon excitation (3.8 and 1.7 nsec, respectively); and both distinct from the typical average lifetime of the retinal background fluorescence (0.2 – 0.4 nsec; reviewed in PMID 28673870).

Conclusions: Based on these results we propose that in vivo imaging of tetracycline-labelled HAP in the outer retina could become a useful tool to monitor mineralization using a fluorescence lifetime ophthalmoscope with multiphoton excitation.

ABSTRACT BODY:

Purpose: Anti-VEGF treatment response is assessed anatomically by changes in the central retinal thickness (CRT) and by BCVA outcomes at 3 months after initial monthly injection. This study aims to characterize treatment outcomes of DME patients with limited early response to anti-VEGF at month (M) 3 using a machine learning (ML) algorithm to quantify fluid on optical coherence tomography (OCT) and analyze features of patients within subcategories.

Methods: A retrospective chart review of treatment naive patients ≥ 18 years diagnosed with DME was conducted. All patients had ≥ 12 months of follow-up after initial anti-VEGF treatment and available OCT scans at baseline (M0), M3, M6, and M12. A ML algorithm, Notal OCT Analyzer, quantified fluid volumes on OCTs of subretinal (SRF), intraretinal (IRF), and total retinal fluid (TRF) at each time point. Patients were categorized as limited early responders (LER) if they had ≤ 10% CST reduction and/or < 5 ETDRS letter gain at M3; the other were early responders (ER). BVA, CST, and fluid change at M12 and M0 were compared between groups. Analysis included the Welch's t-test, Welch's ANOVA, and one-way analysis of means.

Results: The study included 220 eyes (162 LER, 58 ER) then divided into those who satisfied the anatomic criteria (113 aLER, 107 aER), or VA criteria (134 vLER, 86 vER). At M12, BVA and CST outcomes were significant for aLER and aER. The aLER mean letter gain was 1.32 ETDRS and aER was 9.14. The aLER mean CST reduction was 24.94 mm and aER was 129.51 mm. There was no BVA, TRF, and IRF variance across time for LER ($p > 0.1$), while all ER groups varied between M0 and M3 ($p < 0.001$). SRF varied across time for all ER, vLER, and LER. CST had high variance across all groups ($p = 0.008$) except aLER with a low significance ($p < 0.01$).

Conclusions: The M12 outcomes between the LER and ER groups showed significant difference between the aLER and aER indicating worse BVA and CST outcomes for those with ≤ 10% CST reduction at M3. Furthermore, limited BVA improvement after M3 for all LER groups indicates vision is unlikely to improve after M3. Similarly, all ER groups showed minimal fluid, BVA, and CST changes after M3. Thus, the characterization of response type at 3 months of monthly anti-VEGF injections can predict anti-VEGF treatment outcomes in DME patients.

ABSTRACT BODY:

Purpose: Prolonged oxidative stress in the retinal pigment epithelium (RPE) can cause the death of RPE and photoreceptor cells, leading to vision loss in patients with dry-AMD. However, the molecular mechanism(s) of how oxidative stress in the RPE contributes to human retinal cell degeneration is poorly understood. The study aims to investigate the crosstalk between RPE and the retina while RPE is under prolonged oxidative stress.

Methods: We used a mouse model of RPE oxidative stress (Sod2flox/flox/VMD2-cre mice), which were generated by RPE-specific deletion of Sod2, the mitochondrial isoform MnSoD, an oxidative stress response protein. These mice showed progressive retinal degeneration that recapitulates some of the features of dry AMD. To identify a possible mechanism for these pathologies, we harvested eyes from Sod2flox/flox/VMD2-cre mice and age-matched littermate control Sod2flox/flox mice and performed histological, biochemical, and visual function analysis.

Results: Histological and electron microscopic analysis provided important information related to photoreceptor outer segments recycling, structure, and health, where progressive degeneration of the outer photoreceptor segments was observed. However, no changes in the expression of phototransduction proteins were detected. A modest increase in oxidative stress markers was noted. Oxidative stress in the RPE induced the expression of TFEB, one of the key transcription factors that determine the effective lysosomal clearance.

Conclusions: This study establishes a connection between RPE oxidative stress and the induction of lysosomal biogenesis via TFEB. It has broad implications in understanding human inherited retinal degeneration and will help develop novel therapeutics to treat vision loss.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a proliferative retinal vascular disease, typically affecting preterm low birth weight neonates. In high-income countries, ROP has been identified through screening programmes with paediatric ophthalmologist-led clinical examination for at-risk neonates, yet because of a growing survival rate of premature infants globally, the demand for screening is increasing. We explore if a custom deep learning with coding or an AutoML deep learning model without coding can diagnose ROP Plus disease in fundus images.

Methods: A retrospective cohort study of optic disc-centred retinal photographs, acquired using the Retcam Version 2 device (Natus Medical Incorporated©), from preterm neonates fulfilling Royal College of Ophthalmologists screening criteria for ROP screening at the Homerton University Hospital, London, United Kingdom between January 2008 and January 2018. Two models were trained - a custom model with DenseNet architecture, as well as a Google Cloud AutoML Vision model trained through the online interface without the use of coding. The reference standard was derived from a hierarchical grading system: two juniors, both with three years of ophthalmology experience, labelled images as ungradable, normal, Pre-plus or Plus disease with arbitration by a senior paediatric ophthalmologist on disagreements. Our models were trained on a dataset of 6620 posterior pole images of 1370 patients. Model performance was through a split-sample internal validation on 200 images (100 normal, 49 Pre-Plus and 51 Plus) from 111 patients.

Results: On internal validation, the custom coding model had a sensitivity of 39.7%, specificity of 97.3%, area under the curve (AUC) of 0.941, and 95.2% accuracy for normal versus diseased (Pre-Plus and Plus disease) classification. The AutoML model had a sensitivity of 60.3%, specificity of 98.9%, AUC of 0.95, and 96.7% accuracy for normal versus diseased classification.

Conclusions: We demonstrate that the use of custom models, as well as automated machine learning that does not require coding, have similar performance. External validation comparing the two models with independent human graders is still pending.

TITLE: Differential Expression of the Vesicular Inhibitory Amino Acid Transporter (VIAAT)/slc32a Paralogues in Zebrafish Retina

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.L. Stella, A. Ostman, Neural and Behavioral Sciences, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Salvatore Stella: Commercial Relationship: Code N (No Commercial Relationship) | Alexandria Ostman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the retina, the slc32a1 gene or the vesicular inhibitory amino acid transporter (VIAAT) has been of great interest and is expressed at synaptic terminals of horizontal cells in the outer retina and amacrine cells in the inner retina; with GABA having a significant role in both feedback and feedforward signaling in the outer retina driven by horizontal cells, and GABAergic and glycinergic feedback signaling in the inner retina among amacrine cells. Zebrafish are a widely used model for retinal studies and have undergone a gene duplication event that has resulted in the duplication of ~ 50% of all genes. This duplication event has permitted the partitioning of gene function or expression patterns. The goal of this study is to explore the impact of this duplication event on the expression profile of VIAAT paralogues (slc32a1 and si:dkey-126h10.1) in the adult zebrafish retina.

Methods: Adult zebrafish brains or retinas were used to extract RNA, and generate probes for in situ hybridization as described previously (Grillo et al., Purinergic Signal. 2019). Indirect immunofluorescence and confocal microscopy with antibodies targeted to VIAAT, GABA, glycine, and glutamic acid decarboxylase (GAD) were used to characterize the key components of the inhibitory signaling system in the inner and outer zebrafish retina. Ensembl and BLAST were used to identify slc32a1 members. All sequences were compiled and aligned using BLAST, and evolutionary analysis and the phylogenetic tree creation were completed using MEGA (ver. 11), with the human protein sequence serving as the reference in BLAST.

Results: Unexpectedly, we found that the expression slc32a1, the 1st VIAAT homolog was expressed exclusively in the inner retina at amacrine cells, and si:dkey-126h10.1, the 2nd VIAAT homolog was restricted to horizontal cells in the outer retina. This novel observation may relate to the developmental changes that likely occurred during the gene duplication event in teleosts through the segregation of inner and outer retinal circuitry.

Conclusions: This will also serve as an important tool for the development of gene targeted approaches involving VIAAT in the zebrafish retina. Our data suggest that these VIAAT expression patterns may provide the specificity necessary to dissect the cell type specific roles for VIAAT inhibitory neurotransmission in the outer and inner retina.

TITLE: Minimally Invasive Glaucoma Surgery Wet-Lab: A Follow-Up Needs Assessment Survey for Ophthalmology Residents

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Griffin, A. Stefaniak, R. Vasaiwala, M. Chaku, Ophthalmology, Loyola University Health System, Maywood, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Sarah Griffin: Commercial Relationship: Code N (No Commercial Relationship) | Alexis Stefaniak: Commercial Relationship: Code N (No Commercial Relationship) | Roshni Vasaiwala: Commercial Relationship: Code N (No Commercial Relationship) | Meenakshi Chaku: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In 2012 Saheb and Ahmed found that minimally invasive glaucoma surgeries (MIGS) lower intraocular pressure, decrease dependence on medications, and have an excellent safety profile. In 2017 75.5% of glaucoma surgeries performed in the US on Medicare patients 65 years or older in the US were MIGS. A 2020 study surveyed US program directors and found that both didactics and wet labs are used for resident training in MIGS. However, 37% of program directors did not feel that the experience was adequate for independent practice and only 27% felt that MIGS should be an ACGME requirement. Since 2017 Loyola's citywide annual microsurgical wet lab for six Chicago residencies has focused on hands-on training in MIGS to meet the increasing interest amongst residents. During COVID-19, Loyola continued to host our annual wet lab, providing MIGS training virtually. The purpose of this study was to assess residents' perspectives of their current MIGS training and how residents' perspectives have changed since 2017.

Methods: In 2017 and 2020 respectively, 31 and 44 residents of 6 Chicago programs attended our wet lab. Residents were given a pre-wet lab survey regarding their interest in MIGS and training satisfaction. The data collected was anonymous and de-identified. In 2017 data was collected in-person on iPads using RedCap software and in 2020 the data was collected remotely using Qualtrics data collection platform. In both wet labs residents performed various MIGS and intraoperative gonioscopy.

Results: In 2017 and 2020 respectively, 77% and 81% of residents reported that they were interested or very interested in MIGS. In 2017 32% of residents were satisfied by their MIGS training. In 2020, still only 25% of residents were satisfied by their current MIGS training.

Conclusions: Despite widespread use of MIGS in the US and growing interest amongst graduating ophthalmologists, there continues to be a gap between resident interest in MIGS and satisfaction with training during residency. Over the four years, this gap has remained unchanged. A MIGS-based hands-on wet lab experience is one way to improve MIGS training for residents and close the gap between interest and satisfaction with current MIGS resident training.

ABSTRACT BODY:

Purpose: Rabin8, the GEF for the small GTPase Rab8, provides the backbone of the Rab11-Rabin8-Rab8 ciliogenesis complex, which regulates sorting of rhodopsin into transport carriers (RTCs). Membrane association and function of Rabin8 is regulated by NDR2 kinase (aka STK38L), a canine early retinal degeneration (erd) gene. In this study, we continued to investigate the function of the Rab11-Rabin8-Rab8 complex and its control by NDR2 kinase in ciliary trafficking of rhodopsin.

Methods: Human GFP-Rabin8 WT was cloned into the XOP0.8 eGFP-N1 expression vector for the generation of transgenic X. laevis. The following Rabin8 mutants were generated: a phosphomimetic GFP-Rabin8 S272E and the non phosphorylatable GFP-Rabin8 S272A; the Rab8 GEF domain mutants GFP-Rabin8 E192A and F201A; and Rab11 binding mutants GFP-Rabin8 Δ300-305 and GFP-Rabin8 T419A Y423A L428A. The resulting phenotypes were analyzed by confocal microscopy. Interactions of GST-tagged Rabin8 mutants were examined by GST-pulldowns.

Results: Human GFP-Rabin8 WT colocalized with endogenous X. laevis Rabin8. It accumulated at the Golgi exit sites (GES) possibly affecting its own NDR2 phosphorylation and that of the endogenous Rabin8, which accumulated nearby. GFP-Rabin8 WT colocalized with rhodopsin in the Golgi, at the GES and on RTCs. GFP-Rabin8 S272E, a phosphomimetic, colocalized with endogenous Rabin8 at the GES and on RTCs. By contrast, non-phosphorylatable GFP-Rabin8 S272A accumulated at the GES and failed to reach the RTCs. GFP-Rabin8 E192A and F201A, Rab8-GEF mutants, colocalized with rhodopsin in the Golgi, at the GES and on RTCs, which were often enlarged, likely due to the disruption of Rab8 function. GFP-Rabin8 Δ300-305 mutant was cytosolic. GST-pulldowns showed that mutations did not alter the ability of Rabin8 to interact with Rab8 and Rab11. GST-Rabin8 Δ300-305 was likely misfolded, so the cytosolic expression of GFP-Rabin8 Δ300-305 in transgenic rods was likely due to disrupted dimerization, which is essential for its function. We have synthesized GFP-Rabin8 T419A Y423A L428A mutant that disrupts the Rab11 binding but not the Rabin8 dimerization, for immediate transgenesis.

Conclusions: During ciliary targeting, Rabin8 phosphorylation by NDR2 kinase likely occurs at the GES, regulates Golgi exit and directs Rabin8 to the base of the cilium for Rab8 activation. Ongoing experiments will establish the role of Rabin8-Rab11 interaction in rhodopsin ciliary trafficking.

ABSTRACT BODY:

Purpose: To describe the phenotypic and genotypic findings in two siblings with a severe cone dystrophy and electroretinogram (ERG) findings characteristic of CDSRR.

Methods: Over 1600 genetic retinopathy patients attending the Genetic Eye Disease Service at the Royal Victoria Eye and Ear Hospital, Dublin, have been recruited prospectively as part of Target 5000. Testing includes: best-corrected visual acuity (BCVA), Goldmann perimetry, Lanthony D15 colour vision, slit-lamp biomicroscopy, ISCEV clinical standard electrodiagnostics, colour and autofluorescence fundus photography and optical coherence tomography. DNA samples undergo exon sequencing of c. 254 candidate genes using target-capture oligo panels or whole exome sequencing in research and/or accredited facilities. Variants of uncertain significance are subjected to in silico analysis.

Results: Two brothers, 15 and 16 years old respectively, reported life-long reduced vision and photophobia. BCVA was 6/48 and each had red/green colour deficits. ERGs showed delayed rod-isolated responses of low-normal amplitudes and dark-adapted rod-dominated maximal responses of unusually high amplitude. Cone-isolated responses were delayed and markedly reduced in amplitudes. This constellation suggested CDSRR as a likely diagnosis. Genotyping revealed compound heterozygosity for KCNV2 c.1381G>A, p.(Gly461Arg), a known pathogenic variant, and c.1354G>C, p.(Ala452Pro), a previously unreported variant. In silico analyses using SIFT, Mutation Taster and Polyphen 2 predicted the latter to be deleterious.

Conclusions: KCNV2 (OMIM *607604), causative of CDSRR, encodes the subunit Kv8.2 of a voltage-gated potassium channel in rods and cones. Activation is enabled by complex formation with other subunits and expression influenced by transcription factors CRX and NRL. KCNV2 variants underlie up to 4.3% of cone dystrophies. c.1381G>A, p.(Gly461Arg) is the most commonly reported variant. c.1354G>C, p.(Ala452Pro), a previously unreported missense variant, is absent from the gnomAD database and has not been reported in ClinVAR or HGMD. It affects a highly conserved amino acid in the ion transport domain. Two missense variants affecting a nearby codon have been reported to cause CDSRR. Further functional studies are underway, however, this report provides, to the best of our knowledge, the first evidence for pathogenicity of KCNV2 c.1354G>C, p.(Ala452Pro).

ABSTRACT BODY:

Purpose: The perceptual roles of most retinal ganglion cell (RGC) classes are controversial in part because we lack a paradigm for measuring the perceptual consequences of activating cells of only one class in the living primate eye. Recent success in classifying single RGCs with in vivo calcium imaging (McGregor 2018, PLoS One, 13), in vivo optogenetic activation of RGCs en masse (McGregor 2020, Nat. Commun. 11, 1703; Sahel 2021, Nat. Med. 27., 1223), and in vivo targeted excitation of single cones (Harmening 2014, J. Neurosci. 34, 5667) now bring such a paradigm within reach. As a first step, we demonstrate the optogenetic stimulation of single foveal RGCs in the living macaque.

Methods: RGCs in an anesthetized female macaque were stimulated and imaged using adaptive optics scanning light ophthalmoscopy. Co-expression of the optogenetic actuator and calcium indicator was achieved via intravitreal injection of AAV2-CAG-ChrimsonR-tdTomato and AAV2-CAG-GCaMP6s. We selected single RGC somas from those closest to the foveal center because of their large separation from their nearest neighbors (>20 μm). On each trial, the targeted soma was exposed to 12.5 μm diameter flashes (640 nm, 900 μW) of 0.8 second duration. Four consecutive flashes were delivered, each separated by 15s. The GCaMP responses to the flash of both targeted and nearby cells were imaged with a 1° field (488 nm, 25 μW) and the ΔF/F for each soma's response was averaged over the four flashes.

Results: In two cells serving cones at the foveal center, it was possible to record calcium responses in the targeted cell on single trials, a result that was repeatable in the same cells in two sessions one week apart. In the first session, the targeted cell responses showed mean ΔF/F values of 0.314 and 0.177. Nearby cells showed little or no response with a mean of 0.003 (se = 0.008, n = 52, 95% CI [-0.013, 0.018]). In the second session, the same two targeted cells gave values of 0.291 and 0.189. Nearby cells gave a mean value of 0.015 (se = 0.007, n = 66, 95% CI [0.002, 0.028]).

Conclusions: We can directly activate single RGCs in the living eye and measure the resulting calcium signal, the first step toward a method to measure the sensations produced by individual RGCs in the awake behaving monkey. Such a paradigm could also provide valuable information for RGC-based optogenetic or optoelectronic vision restoration therapies.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) are a large group of genetically heterogeneous disorders that result in severe vision loss. Over 150 unique gene mutations in over 100 genes have been associated with RP, with high variability in disease onset, severity, and progression. Our prior and recent Ingenuity Pathway Analysis(IPA) revealed that Nr2e3 regulates several key biological networks that are critical to maintaining homeostasis in the retina including phototransduction, survival, apoptosis, immunity, oxidative stress, ER stress, neuroprotection and metabolism. In this study we determine the expression profiles of the key retinal transcription regulators such as Nr2e3, Nr1d1, neural retinal leucine zipper (Nrl), Cone-rod homeobox (Crx), retinoic acid receptor related orphan receptor alpha (Rora) and thyroid receptor beta (Thrb) in multiple RP models before and after treatment with AAV-Nr2e3 therapy.

Methods: Neonatal and developed rd1$^{-/-}$, Rho $^{-/-}$, rd16$^{-/-}$, Rho^{P23H}, and rd7 $^{-/-}$ AAV-Nr2e3 treated and untreated mice were euthanized and eyes were enucleated according to IACUC guidelines. RNA was isolated from retinas (N=7) at P0, P7, and P30. Gene expression profiling of key regulator genes were carried out by RNA Seq and quantitative real-time PCR.

Results: Overall, there is a significant downregulation in expression of key retina transcription factors in each model. This shift in turn causes misregulation of key homeostasis gene networks as disease progresses in each model. AAV-Nr2e3 therapy attenuates retinal degeneration and results in increased expression of key retinal transcription factors and reset of retina homeostasis.

Conclusions: This is the first report evaluating the impact of transcriptome kinetics on retinal degeneration. The primary mutation causes a shift of transcription kinetics, forcing the retina to make a save or abort decision early in disease, leading to progressive photoreceptor degeneration. This combinatorial mutational load including the primary mutation and key retinal transcription factor modulation determines phenotypic outcome of each disease. This study further shows the profound impact of AAV-Nr2e3 modifier gene therapy in attenuating retinal disease. This study uncovers how altered transcriptome kinetics impacts pathogenesis of retinal degeneration and therapeutic intervention resets these transcriptomes.

ABSTRACT BODY:

Purpose: Recent studies have demonstrated the presence of abnormalities in the macular retinal vessels of patients with open-angle glaucoma. We performed a prospective, observational cross-sectional study to determine whether changes in macular retinal vessel density (VD) were associated with steady-state pattern electroretinogram (ssPERG) parameters, retinal nerve fiber layer (RNFL) thickness, and ganglion cell inner plexiform layer (GCL-IPL) thickness measurements in glaucoma suspects (GS).

Methods: 14 patients (19 eyes) with normal Humphrey 24-2 visual field tests, suspicious optic nerve head findings and refractive errors < ± 5.0 Diopters were enrolled in the study conducted at Manhattan Eye Ear and Throat Hospital. Participants underwent ophthalmological examination and tests on Humphrey Field Analyzer (HFA), Diopsys NOVA PERG, SPECTRALIS® OCT, and the Cirrus HD OCT-A Angioplex devices. VD of the retinal arteries was calculated using the vessel analysis plug-in on ImageJ. An inner circular boundary with a diameter of 0.6mm was used to exclude the foveal avascular zone and a 1mm (VD1mm) or 2mm (VD2mm) diameter circle was used as an outer boundary. Correlation analyses were used controlling for age and spherical equivalent.

Results: Results were gathered from 19 eyes of 14 patients aged 59.64 ± 14.16 years of age, with mean IOP 17.29 ± 3.98 and HFA 24-2 mean deviation 0.51 +/- 0.72. VD1mm was negatively correlated with FAZ area ($r=-0.684$, $p<0.01$) and positively correlated with PERG parameters Mag ($r=0.665$, $p<0.01$), MagD ($r= 0.682$, $p<0.01$) and MagD/Mag ratio ($r= 0.599$, $p<0.05$). VD1mm was also positively associated with nasal-inferior RNFL thinning, although the relationship was not significant ($r=.483$, $p=0.068$). VD2mm was positively correlated with nasal-superior RNFL thinning ($r=0.693$, $p<0.01$). No significant associations between VD and GCL-IPL thickness were found.

Conclusions: This study is the first to demonstrate that reductions in macular VD correlate with abnormal ssPERG parameters and RNFL thinning in patients with GS. Macular VD decrease was detected sooner than GCL-ILP thickness changes, which is most likely associated with early stages of disease. Further studies are necessary to determine the interactions between GCL-IPL, PERG and VD across the disease spectrum and by sectors.

ABSTRACT BODY:

Purpose: Evaluate the impact of headache or visual impairment adverse events (AEs) following active treatment with AGN-190584 on patient reported outcomes (PROs) metrics in the GEMINI 1 and GEMINI 2 phase 3 clinical trials.

Methods: Post hoc analysis of PROs stratified by headache and visual impairment (characterized as dimness of vision or jumping vision) AE occurrence were conducted on pooled data from the identical GEMINI 1 and GEMINI 2 phase 3 studies. Least squares mean (LSM) change from baseline in PRO domain scores for the Presbyopia Impact and Coping Questionnaire (PICQ) and Presbyopia Patient Satisfaction Questionnaire (PPSQ) were compared between study participants in the active treatment group (AGN-190584) who did or did not experience headache or visual impairment of special interest over the course of the 30 day clinical trials. Data were stratified by the number of lines gained (≥1, ≥2, or ≥3) in mesopic Distance Corrected Near Visual Acuity (DCNVA) at hour 3 on day 30.

Results: There were no significant differences in the PICQ and PPSQ domain LSM change scores between study participants who did or did not experience a headache AE regardless of whether the study participants achieved a ≥1, ≥2, or ≥3-line improvement in mesopic DCNVA at hour 3 on day 30. Similarly there were no significant differences in the PICQ and PPSQ domain LSM change scores between study participants who did or did not experience a visual impairment AE regardless of whether the study participants achieved a ≥1, ≥2, or ≥3-line improvement in mesopic DCNVA at hour 3 on day 30. Table 1 shows the PICQ and PPSQ results for the participants who achieved a ≥3-line improvement as that was the primary efficacy endpoint of the studies.

Conclusions: No observed differences in the domain change scores between study participants who did or did not experience AEs of headache or visual impairment suggests that these AEs did not materially impact patient reported benefits in study participants who received AGN-190584.

ABSTRACT BODY:

Purpose: Levodopa restores retinal dopamine levels in diabetic retinopathy and ameliorates retinal dysfunction in both rodent models and clinical studies. However, these studies involved short-term treatment prior to the onset of retinal vascular defects. In this study, we evaluated the protective effect of levodopa treatment in later stages of DR in a diabetic rat model when started after detection of early retinal dysfunction.

Methods: Hyperglycemia (≥250 mg/dL) was induced in a subset of 2-month-old male Long Evans rats via streptozotocin (STZ) injection (100 mg/kg). Oral administration of levodopa (10 mg/kg levodopa, 2.5 mg/kg carbidopa, 0.8 g/kg powdered peanut butter dissolved in 1:1 water) or peanut butter vehicle (0.8 g/kg powdered peanut butter in 1:1 water) for 5 days per week began at 6 weeks post-STZ injection and continued until 24 weeks post-STZ injection. Rats were assessed with full-field electroretinogram and optomotor response prior to STZ injection and for every 4 weeks following hyperglycemia. Mixed-effects linear regressions were used to compare the effect of diabetes and levodopa treatment on outcome measures.

Results: Levodopa treatment improved spatial frequency thresholds in diabetic rodents (n=9) relative to vehicle-treated diabetic rodents (n=9) by 30% (at 24 weeks post-STZ injection, 0.390±0.008 vs. 0.298±0.008 c/d, $p<0.001$). Levodopa similarly improved contrast sensitivity thresholds in diabetic rodents by 35% during treatment period (at 24 weeks post-STZ, 5.018±0.217 vs. 3.212±0.139 a.u., $p=0.004$). In response to dim stimuli, dark-adapted, levodopa-treated diabetic rodents had improved oscillatory potential delays compared to vehicle-treated rodents at 24 weeks post-STZ injection (57.72±1.09 vs. 67.50±2.53 ms, $p=0.008$). Oscillatory potential delays in response to dark-adapted bright stimuli were worsened by diabetes but were not improved with levodopa treatment.

Conclusions: Levodopa maintained its protective effect on retinal and visual function to 24 weeks post-STZ when vascular defects are present in the STZ-induced diabetic rat. Future work will look at vascular biomarkers to evaluate the effect of dopaminergic treatment on vascular defects in DR.

TITLE: Outcomes of Eyes Undergoing Silicone Oil Removal Following Complex Rhegmatogenous Retinal Detachment Repair

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.C. Stenz, The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, Texas, UNITED STATES|E.C. Stenz, C.C. Wykoff, S.B. Patel, Retina Consultants of Texas, Houston, Texas, UNITED STATES|C.C. Wykoff, S.B. Patel, Blanton Eye Institute, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Emma Stenz: Commercial Relationship: Code N (No Commercial Relationship) | Charles Wykoff: Commercial Relationship: Code N (No Commercial Relationship) | Sagar Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The use of silicone oil (SO) during rhegmatogenous retinal detachment (RRD) surgery allows for prolonged retinal tamponade. While SO removal (SOR) is performed to optimize visual function, there are incompletely defined risks such as re-detachment (re-RD) associated with SOR. The current study characterizes rates of re-RD and functional outcomes following SOR.

Methods: Data was retrospectively collected from an urban retina practice with 14 physicians. Inclusion criteria were SO placement (SOP) during an RRD repair followed by SOR from 2016-2021. Exclusion criteria were vitreoretinal surgery performed outside the practice and post-operative follow-up periods of <3 months. Analyzed parameters included epidemiological data, intraoperative variables, and post-operative outcomes. Statistical analysis included one-way ANOVA with Tukey HSD testing (significance defined as $p<0.05$).

Results: 89 eyes of 88 patients underwent SOR following ≥1 RRD repair with SOP. 77 of 89 eyes (86.5%) did not undergo further RRD surgery following SOR; of this group, 2 eyes did not achieve reattachment due to persistent subretinal fluid (SRF) and 1 eye underwent enucleation due to Proteus spp. panophthalmitis. Additional RRD repairs were required by 12 of 89 eyes (13.5%); of this group, 2 eyes received gas tamponade while 10 eyes received SOP in re-surgeries. 9 of 10 eyes receiving SOP a second time did not undergo further SOR, while 1 eye proceeded successfully with a second SOR (Table 1). Only 1 of 12 eyes experiencing an additional RRD repair remained unattached due to persistent SRF. Visual acuity (VA) among eyes without additional RRD repairs following SOR improved by 0.32logMAR from SOR (baseline VA) to final follow-up ($p<0.05$), while VA among eyes undergoing ≥1 additional RRD repair minimally improved or worsened from baseline (Table 2).

Conclusions: This study characterized re-RD rates and visual outcomes among eyes undergoing SOR after RRD repair. VA improvement was observed among eyes that did not undergo additional surgeries following SOR. Further work comparing the risks of re-RD with the functional benefits following SOR may help guide clinical management.

ABSTRACT BODY:

Purpose: APDs are a condition when there is an unequal response to a light stimulus, indicating unequal optic nerve / retinal disease. Health care providers screen for APD by performing a swinging flashlight test (SL test). However, SL test can be difficult to execute causing inter-observer variability and quantification of APD, from the author's experience, is seldom done. QP may solve shortcomings of SL test by objectively quantifying pupil responses to a light stimulus, and may have better sensitivity.

Methods: Retrospective review of 456 patients presenting for pre-surgical evaluation in a two physician cataract and refractive practice. Patients over 18 years of age without iris / pupil damage had QP via the EyeKinetix II (Konan Medical) in a room at 35 lux. Values over 0.5 on the Eyekinetix RAPD score (ERS) were considered indicative of an APD. (Note: Konan uses ERS of 0.3 for possible APD; we chose 0.5 based on instrument reproducibility tests). A subset of APD patients were referred out for additional workup with their consult letters read for documented APD.

Results: Of 456 patients, 56 had ERS above 0.5. Attributed causes: glaucoma (28), retinal detachment (5), NAION (3), Thyroid Eye Disease (2), ARMD (2), workup pending (8) and other (8) including CRAO, pituitary tumors, and multiple sclerosis. Of 36 patients referred, 4 had APD detectable by sub-specialists (smallest ERS by sub-specialist was 0.91). Subsequent workup showed all patients had abnormal visual fields, and/or clinically significant thinning of retinal nerve fiber layer and/or ganglion cell layer. Insufficient ERS threshold was observed in 3 patients with pseudotumor, 2 with strokes, and 1 with papilledema.

Conclusions: QP appears to be an indispensable tool for screening patients. While bilateral diseases may not trigger APD, elevated ERS values are strong indicators further workup is needed. QP appears more sensitive to APD detection vs health care provider SL test. Quantification of APDs by QP makes QP a useful adjunct in clinical decision-making processes for further testing (e.g. OCT, Visual Field, etc) and may make QP suitable for progression monitoring. Additional research is needed to study further benefits of QP amongst different patient populations as well as longitudinal evaluations.

TITLE:

In vivo measurement of the light distribution in the focal plane of an AOSLO focused at inner and outer retina

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Rogers, Morgridge Institute for Research, Madison, Wisconsin, UNITED STATES|N. Stangel, Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|A. Dubra, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Jeremy Rogers: Commercial Relationship: Code N (No Commercial Relationship) | Nickie Stangel: Commercial Relationship: Code N (No Commercial Relationship) | Alfredo Dubra: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Adaptive Optics Scanning Light Ophthalmoscopy (AOSLO) provides exceptional contrast of cone photoreceptor outer segments using reflectance confocal imaging due to the high reflectivity afforded by the cone geometry. Imaging modalities that provide contrast of other structures is more challenging, but nonconfocal split detection has proven effective at imaging inner segments and vasculature, and has been used to image Retinal Pigment Epithelium and ganglion cells. However, optimizing the detection geometry remains a largely brute force effort of trial and error. We hypothesize that measurement of the distribution of light in the focal plane at different retinal layers would provide valuable guidance for designing detector geometry to optimize contrast in retinal structure of interest.

Methods:

We previously demonstrated a custom microscope using a descanned imaging detector for ex vivo imaging that allowed exploration of image contrast by creating virtual nonconfocal geometries in post processing. While image sensors are far too slow to image the light distribution at each pixel in an AOSLO image in vivo, measurement of the statistical distribution of light is possible. A scientific CMOS operating at 13kHz frame rate (small ROI) was placed at the confocal image plane of an AOSLO using an integration time of 39us. A human subject was imaged with the AOSLO focused on photoreceptors (Fig. 1a) and inner retina (Fig. 1b) at 2 degrees temporal from the fovea. Each frame captured approximately half of the period of the 13kHz resonant scanner. Intensity thresholds were used to select only the frames corresponding to the pixels at the edge of the AOSLO image (Fig. 1c).

Results:

The average intensity (Fig. 1d-e) and coefficient of variation (Fig. 1f) are shown. The mean intensity peak drops when focused at the inner retina as expected and the distribution is broader. Since the the signal must vary as across pixels to produce image contrast, the coefficient of variation is used as an indication of contrast. C.V. is higher at the center when focused on photoreceptors, but when focused on the inner retina, the C.V. is higher at larger detector seperations.

Conclusions:

Measurement of the light distribution at the AOSLO focal plane is possible with a descanned CMOS detector and can provide guidance to optimize detection geometry for improved nonconfocal detection at different retinal layers.

TITLE: BMP3 suppresses embryonic corneal myofibroblast phenotype by promoting focal adhesion turnover and αSMA fiber disassembly

SESSION TITLE: Corneal stromal biology, wound healing modulators, and regeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: P. Lwigale, J. Spurlin, Biosciences, Rice University, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Peter Lwigale: Commercial Relationship: Code N (No Commercial Relationship) | James Spurlin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Acute damage to the cornea often initiates drastic tissue remodeling, resulting in fibrotic scarring that disrupts light transmission and precedes vision impairment. Very little is known about the factors that can mitigate fibrosis and promote scar-free cornea wound healing. Here, we sought to elucidate the mechanistic regulation of transient myofibroblast differentiation during scar-free embryonic cornea wound healing.

Methods: Wounded embryonic chicken corneas were analyzed for BMP and TGFβ ligand expression by qPCR and in situ hybridization. Signal transduction of these pathways was assessed by immunohistochemical staining for respective pSMADs on histological sections of healing embryonic tissues. Primary chick embryonic keratocytes were stimulated with recombinant BMP and TGFβ ligands to determine induction and turnover of the myofibroblast phenotype.

Results: We found that alpha-smooth muscle actin (αSMA)-positive myofibroblasts are superficial and their presence inversely correlates with wound closure. Expression of TGFβ2 and nuclear localization of pSMAD2 were elevated during myofibroblast induction. BMP3 and BMP7 were localized in the corneal epithelium and corresponded with pSMAD1/5/8 activation and absence of myofibroblasts in the healing stroma. In vitro analyses with primary keratocytes revealed that BMP3 inhibits the persistence of TGFβ2-induced myofibroblasts by promoting disassembly of focal adhesions and αSMA fibers. This was confirmed by the transient expression of vinculin in vivo.

Conclusions: Our data highlight a novel mechanism to inhibit myofibroblast persistence during cornea wound repair. Myofibroblasts are transient in wounded embryonic corneas and correlate with upregulation of pSMAD1/5/8. Stability of αSMA fibers in cultured myofibroblasts requires mature focal adhesions. BMP3 drives the disassembly of αSMA stress fibers by promoting the dissolution of focal adhesion complexes.

ABSTRACT BODY:

Purpose: Aging is a leading risk factor for retinal degenerative disease. A better understanding of the mechanisms of aging could lead to treatments for age-related retinal disease. When DNA methylation patterns are observed genome wide over the course of an individual's lifetime, these marks change in a predictable way, and can be used to generate a DNA methyl-aging clock (DNAmA Clock) in humans and mice. Trisomy of the 21st chromosome (T21) causes premature aging and early onset of age-related retinal diseases including cataracts, macular degeneration and glaucoma. Adults with T21 have also been shown to have an accelerated DNAmA Clock. We show that age acceleration of T21 tissues already occurs in the fetal retina. If we can better understand the molecular mechanisms of accelerated aging in T21 individuals, we may be able to better understand mechanisms of age-related retinal diseases in both T21 and normal individuals.

Methods: To identify the DNA-methyl age, we extract genomic DNA and profile the CpG methylated regions using the Infinium MethylationEPIC Kit for human samples or the mammalian methylation array developed by Arneson et al., 2021 for mouse samples. We then calculate the DNA-methyl age based on comparison to the Horvath Pan-Tissue clock. We apply this assay to normal and T21 human retina, and normal and T21 mouse retina and other tissues. We use the mouse model of T21 called Ts65Dn.

Results: We observe a robust DNA-methyl age acceleration in T21 fetal human retinal samples when compared to age matched controls. To further understand the region of the 21st chromosome that is important for age acceleration, we perform similar analysis of the retina from the Tn65Dn mouse model of T21, and also observe robust age acceleration in Tn65Dn mice compared to controls. Other tissues in Tn65Dn mice at various ages also show an accelerated aging profile in the Horvath Pan-Tissue clock.

Conclusions: We show that the DNAmA Clock is accelerated in the fetal retina of humans with T21. Additionally, mice with a homologous region of the human 21st chromosome have an accelerated DNAmA Clock. These results indicate that the age-acceleration that occurs in T21 humans is also present in mice and will allow future studies to better understand the molecular basis of age acceleration and potentially develop new approaches to age-related disorders, such as macular degeneration.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis (LCA) is a debilitating eye disorder and is considered one of the most severe forms of retinal degeneration causing severe vision loss at infancy. Mutations in CEP290 (LCA10) are the most frequent cause of LCA and account for > 26% of all cases. Adeno-associated viral (AAV) vectors are currently the most efficient vectors for gene delivery to the retina. However, the CEP290 gene is too large to be packaged into standard AAV vectors, creating a challenge for the development of a LCA10 gene therapy. We designed a mutation-independent gene therapy delivered with an AAV vector to treat LCA10.

Methods: We designed shorter versions of CEP290 (miniCEP290) under photoreceptor-specific promoters that can be delivered using AAV vectors. Cep290-mutant mice ($Cep290^{rd16}$) were injected in the subretinal space at postnatal 10 days. Photoreceptor response to light was measured by electroretinography (ERG). Retinal structure and protein trafficking were evaluated by immunofluorescence using specific marker antibodies.

Results: After demonstrating the efficiency of a CEP290 minigene [CEP290 amino acid 580-1180 domain] under the control of a ubiquitous promoter to enhance function and survival of photoreceptors in neonatal $Cep290^{rd16}$ only until 5 weeks of age, this current study ‘s goal was to improve the efficacy of the miniCEP290 approach and optimize protein expression. We show that the expression of CEP290-580-1180 under the control of the rhodopsin kinase promoter improved the ERG response for both rod and cone photoreceptors by ~1.5 folds. Further, modification of the miniCEP290 gene construct with different CEP290 domains improved the photoreceptor structural and functional rescue by ~500% in the $Cep290^{rd16}$ mice. We also show that the expression of the new miniCEP290 prolonged the survival and improved the protein trafficking defects, in transduced photoreceptors.

Conclusions: Our preliminary results indicate that miniCEP290 approach with conventional AAV vectors may have the potential for mutation-independent gene therapy in LCA10 patients. These studies may also pave the way to develop new minigene therapies for retinal degenerative diseases caused by mutations in other large genes including Stargardt disease and Usher Syndrome, which are not currently amenable to treatment using conventional AAVs.

ABSTRACT BODY:

Purpose: The Democratic Republic of Timor-Leste is a geographically isolated but ethnically diverse population. Prior research has shown that ocular disease in Timor-Leste varies from developed countries. Although uncorrected refractive error is a common cause of low vision in this population, the types and prevalence of refractive error has not been well characterized.

Methods: Individuals ≥40 years were recruited from Timor-Leste via a population-based cross-sectional survey using multistage cluster random sampling described previously. Autorefraction was performed as part of a full eye examination which included magnified examination of the anterior segment and dilated indirect ophthalmoscopy. Data on age, gender, height, weight, and smoking status were obtained. Descriptive statistics were calculated in Excel and regression analyses were performed using R.

Results: Autorefraction was performed on 578 individuals ≥40 years (273 males, median 52 years). After excluding eyes with cornea or lens opacities, refraction data were available for 1051 eyes (526 OD, 525 OS) of 552 individuals. Spherical equivalent (SE) ranged from -7.5 to 10.12 D. Myopia (SE ≤-1.0D), hyperopia (SE ≥ 1.0 D), and astigmatism (|cylinder| ≥ 1.0 D) were present in 236 (22.4%), 120 (11.4%), and 238 (22.6%) eyes, respectively. Anisometropia (≥ 1.0 D) was present in 17.8% of individuals where autorefraction was available for both eyes. Moderate myopia (3-6 D), high myopia (≥6 D), and high hyperopia (≥3 D) were found in 70 (6.6%), 9 (<1%), and 6 (<1%) eyes, respectively. Neither the presence nor degree of myopia were associated with increased education, BMI, or smoking status, but both were associated with increasing age.

Conclusions: Characterization of refractive error in the Timorese shows a lower prevalence of myopia than developed countries such as the United States or Singapore but the prevalence is comparable to similar populations in Southeast Asia/Oceania. Specifically, the observed prevalence of 22% was nearly identical to that found in individuals ≥40 years in a rural population on Sumatra. Similar to the Sumatran population, prevalence of myopia increased with older age in the Timorese, possibly related to cataract formation. Further work is ongoing to determine the contributions of both environmental factors and genetics on the low prevalence of myopia identified in the Timorese.

ABSTRACT BODY:

Purpose: To report on visual performance over time with traditional scleral lens (tSL) and wavefront-guided scleral lenses (wfgSL) in patients with keratoconus (KC).
Methods: 11 eyes of 8 patients diagnosed with KC were fit with a tSL. After the tSL was finalized, a comprehensive wavefront aberrometry system (X-Wave, Ovitz, Rochester, NY) was used to create a wfgSL (ARES, Ovitz, Rochester, NY). A crossover was performed, best-corrected lens visual acuity (BCLVA) and total higher-order root mean square (HORMS) were compared between the tSL and wfgSL at dispense and after 1-month of lens wear.
Results: When comparing wfgSL to tSL, at dispense, there was a 0.1 ± 0.1 logMAR ($p < 0.01$) improvement in BCLVA and a 0.58 ± 0.29 μ ($p < 0.01$), a 49 ± 13% improvment in HORMS. At 1-month follow-up there was a 0.2 ± 0.1 logMAR improvement ($p < 0.01$) in BCLVA and a 0.54 ± 0.20 μm ($p < 0.01$), a 48 ± 9% improvement in HORMS. No eyes lost lines of visual acuity at dispense or at the 1-month follow-up.

At dispense of the wfgSL, 3 of 11 eyes showed no improvement in BCLVA. At 1-month follow-up, all 3 eyes showed a 0.1 logMAR improvement without additional improvement in HORMS.

Of note, at the dispense of the wfgSL, 1 of the 11 eyes showed a 0.1 logMar improvement in BCLVA, and at the 1-month follow-up, the same eye showed an additional 0.3 logMar lines and a 0.22 μ, 12% improvement in HORMS. Post analysis of this improvement correlated to lens malposition at dispense and correct positioning at the 1-month follow-up.
Conclusions: When compared with tSL, wfgSL reduced HORMS and improved BCLVA. One month after initiating wfgSL wear, BCLVA continued to improve at the follow-up visit without change in HORMS. This improvement is likely secondary to neural adaptation to wfgSL optics. Further studies are needed to understand the role of neural adaptation in wfgSL.

ABSTRACT BODY:

Purpose: Although it is well established that photoreceptor death underlies retinal degeneration (RD), the pathological mechanism(s) remain unclear. We hypothesize that aberrant energy metabolism in the retinal pigment epithelial (RPE), results in nutrient deprivation in the retina and contributes to pathology in SFD.

Methods: Proteomic and metabolic analysis of RPE and retinas from mice expressing S179C TIMP3 and age-matched littermate controls was performed. To directly explore metabolic alterations, targeted metabolomics was performed via gas chromatography-mass spectroscopy (GC-MS) with $^{13}C_6$ glucose isotopic tracing on murine SFD RPE and retina. Retina and RPE were isolated and separately incubated in media containing $^{13}C_6$ glucose for 24 hours following which intra and extra cellular metabolites were extracted with 70% methanol. Metabolite abundance and isotopic distribution of metabolites were quantified using GC/MS and Agilent MassHunter. Finally, IsoCor software was used to correct for natural isotopic abundance.

Results: Proteomic analysis identified changes in several metabolic pathways suggesting metabolic dysfunction in TIMP3 S179C RPE.Targeted metabolomics demonstrated an increased abundance of extracellular M3 labeled lactate along with intracellular TCA cycle intermediates, indicative of increased RPE glycolytic flux, suggesting metabolic dysfunction. Mass isotopic distributions reveal minimal changes which suggests that TCA flux (reflective of rate of metabolite production and breakdown) is unperturbed. In the retina, we observed decreased M3 lactate enrichment intracellularly, characteristic of decreased glycolytic flux. A decrease in abundance of retinal intracellular TCA cycle intermediates was also observed with increased enrichment of M4 glutamate, M3 fumarate and M3 malate. This suggests major perturbation of TCA cycle operations.

Conclusions: In mice expressing SFD-associated Timp3 mutations, the RPE and retina both display aberrant energy metabolism. RPE exhibits an increased glycolytic flux while the retina shows a decreased glycolytic flux along with increased TCA cycle flux. This adds to the growing body of evidence implicating metabolic dysfunction in retinal degeneration and opens the door to unique hypotheses of metabolic changes following extracellular matrix disruptions.

TITLE: Neural recordings of extraocular muscle motoneurons do not show evidence for selective innervation of muscle compartments

SESSION TITLE: Neurophysiology and Treatments of Binocular Vision Disorders

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Adade, V.E. Das, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Samuel Adade: Commercial Relationship: Code N (No Commercial Relationship) | Vallabh Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Selective innervation of extraocular muscle (EOM) compartments may explain the observation made via MRI that certain horizontal recti compartments may contribute to specific vertical eye movements such as vertical vergence and that not all compartments of the cyclovertical EOMs contribute to all vertical eye movements. We investigated the discharge characteristics of EOM motoneurons (MN) during vertical vergence and vertical smooth-pursuit for evidence of selective innervation of EOM compartments. Our hypothesis was that selective innervation of compartments would manifest as a sub-population of horizontal MN that are modulated during vertical vergence and a sub-population of cyclovertical MNs that are modulated during vertical smooth-pursuit but not vertical vergence.

Methods: We recorded from all EOM MN populations in the abducens, oculomotor and trochlear nuclei as two non-human primates performed vertical vergence and vertical smooth-pursuit. The relationship between MN firing rate and horizontal/vertical eye parameters of the innervated eye during each task was determined using multiple linear regression analysis by fitting the data to the equation FR= K_v*(vert. eye pos.) + K_h*(horiz. eye pos.) + R_v*(vert. eye vel.) + R_h*(horiz. eye vel.) + B. Position (K_h, K_v) and velocity sensitivities (R_h, R_v) were considered significant if the 95% confidence interval did not include zero.

Results: We did not find different subpopulation of EOM MNs with different responses during vertical eye movement tasks where some EOMs compartments have been previously found to contract and relax differentially. Thus 28 of 30 abducens MN recorded showed no significant modulation in relation to vertical eye position during vertical vergence and all 30 cells did not modulate during vertical smooth-pursuit. All 149 cyclovertical MN in our sample discharged in relation to vertical eye position during vertical smooth-pursuit (Mean K_v = 4.7 spk/s/°). 147 out of the 149 cyclovertical MN (35/35 IO, 27/27 SO, 41/41 SR, and 44/46 IR) modulated during vertical vergence with mean K_v of 6.2 spk/s/°. Analysis of medial rectus MNs is ongoing.

Conclusions: Our data suggests that the EOM compartments are not selectively innervated and the observed differential contractility of EOM compartments is due to other mechanisms.

ABSTRACT BODY:

Purpose: Photoreceptor degeneration leads to acquired blindness, and it is common in conditions such as retinitis pigmentosa, retinal toxicity, and age-related macular degeneration. Drugs that protect the retina from photoreceptor loss are much needed, as most retinal degenerative diseases have no treatment. We aim to seek effective pharmacological treatments to prevent retinal degeneration using target-based and phenotypic strategies.

Methods: Lead compounds were identified using small molecule drug screening targeting rhodopsin homeostasis, and one compound was identified from aging studies in other organs. The leads were tested firstly in immortal mammalian stable cells in vitro, and they were then studied using retinal explant culture. Finally, the most efficacious compounds were studied in vivo using systemic or intraocular administrations to rodent models of retinal degeneration ($Rho^{P23H/+}$ knock-in mice and aged Fischer344 rats). Efficacy and mechanism of actions of compounds were evaluated using combined methods of electroretinogram (ERG), optic coherence tomography (OCT), immunohistochemistry, RNA-seq, and immunoblots.

Results: Three types of retinal protecting agents were identified: 1) non-retinoid chaperones of rhodopsin; 2) selective inducers of misfolded rhodopsin clearance; and 3) anti-aging purine metabolite against age-related photoreceptor degeneration.

Conclusions: We showed proof-of-principle evidence that photoreceptor degeneration due to RHO misfolding mutations can be rescued by restoring proteostasis using small molecule chaperones or inducers of misfolded protein clearance. Age-related photoreceptor loss can be rescued by oral administration of an anti-aging purine metabolite.

TITLE: Rete Ridge Structures Form Meibomian Gland Distal External Duct Wall and Basal Epithelial Layer

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.L. Maskin, Dry Eye and Cornea Treatment Center, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure: Steven Maskin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate potential relationship between lid margin rete ridges (RR) and meibomian gland (MG) external duct wall.

Methods: Retrospective volume evaluations of upper lid margin confocal microscopy (CFM) at 2 micron depth intervals down to 120 um depth to evaluate spatial relationships between above structures. Eight glands from eight lids of eight patients (M:F = 1:7) whose average age was 51.1 (range 26-74 years) were evaluated.

Results: Each confocal evaluation demonstrated typically round RR in peri-orifice position undergoing morphologic differentiation with progressive depth characterized by ovalization and flattening. The dermal – epidermal basement membrane of the RR differentiates into the MG extermal duct wall while the epithelial cell projections of the RR become the basal epithelial layer.

Conclusions: Rete Ridge examination using volume CFM indicates a role of these structures in the development of the MG external duct wall and basal epithelium. As the RR is known to provide stem cell activity in skin, this finding strongly suggests the RR is likely to provide similar activity for MG.

ABSTRACT BODY:

Purpose: Transmembrane Protein 135 (Tmem135) is critical for controlling retinal aging in mice. For example, Tmem135 mutant mice develop age-dependent photoreceptor pathologies whereas mice overexpressing wild-type Tmem135 (Tmem135 TG) display age-dependent RPE pathologies. Changes in mitochondrial dynamics correlate with the ocular pathologies in Tmem135 mutant and TG retinas, but the molecular mechanism of how Tmem135 maintains mitochondrial dynamics is unknown. It has been shown that peroxisomal changes can affect mitochondrial dynamics. In this study, we investigated whether peroxisomal changes are observed in Tmem135 mutant and TG mice.

Methods: Tissues including the neural retina, eyecup, liver and heart were collected from 10-week-old WT, Tmem135 mutant, and Tmem135 TG mice for Western blot analysis and immunohistochemistry to assess peroxisomal membrane protein 70 (PMP70), an indicator of peroxisome number. Additional tissues were collected for lipidomics to assess peroxisomal function.

Results: We found increased PMP70 in the neural retinas and eyecups of Tmem135 mutant mice. In contrast, PMP70 was decreased in the neural retinas and eyecups of Tmem135 TG mice. We analyzed our retinal lipidomics datasets for lipids derived from peroxisomal products such as those containing long-chain polyunsaturated fatty acids (PUFAs) (i.e. C22:5 and C22:6). Strikingly, 62.5% of the downregulated lipids in the Tmem135 mutant retinas contained either C22:5 or C22:6 PUFAs. In contrast, 46% of the upregulated lipids in the Tmem135 TG retinas contained either C22:5 or C22:6 PUFAs. We confirmed these peroxisomal changes in the livers and hearts of Tmem135 mutant and TG mice.

Conclusions: Our results indicate peroxisome number was inversely-correlated with the amount of functional TMEM135. The changes in peroxisome numbers were associated with global lipidome alterations in Tmem135 mutant and TG retinas. In particular, the concentrations of lipids containing C22:5 or C22:6 PUFAs were correlated with the amount of functional TMEM135, suggesting TMEM135 has a role in peroxisomal PUFA metabolism. Together, our study indicates the importance of TMEM135 in peroxisomal homeostasis that may contribute to retinal mitochondrial dynamics and aging in the murine retina.

ABSTRACT BODY:

Purpose: Significant evidence supports the benefits of consuming omega-3 fats, i.e., phospholipids containing DHA (Docosahexaenoic Acid), for human health. DHA is highly concentrated in the brain and retina despite the fact that it cannot be synthesized in these tissues and has to be transported across the blood-brain and blood-retina barrier (BRB). Mechanisms responsible for DHA transport and its retention behind BRB are poorly defined. Previous studies showed that disruption of lysophosphatidylcholine transport leads to DHA depletion, which was accompanied by upregulation of transcriptional factors, the Sterol Regulatory Element-binding Proteins (SREBPs), and might hint at their potential role in the regulation DHA levels. Here, we used mouse genetics to probe the contribution of basal activity of SREBPs in setting the fatty acid composition of phospholipids in the retina.

Methods: To impair SREBPs' activity, we knocked out SREBP cleavage-activating protein (SCAP) specifically in the retina. The phospholipid and fatty acid analysis was performed using mass spectrometry. The retinal health, function, and structure were assessed with Optical Coherence Tomography (OCT), fluorescein angiography, electroretinography (ERG), and immunostaining. RNAseq was used to study transcriptional changes.

Results: Lipidomics analysis of retina-specific SCAP knockout mice showed reduced levels of docosahexaenoic (DHA), arachidonic (AA), and monounsaturated (MUFA) fatty acids, resulting in a simpler fatty acid profile with higher content of saturated fatty acids. Removal of SCAP also led to progressive thinning of the retina and vasculature defects reminiscent of Retinal Angiomatous Proliferation (RAP). Changes in fatty acid composition were different from mice which lack a receptor protein Mfsd2a transporting lysophosphatidylcholine.

Conclusions: We found that the basal activity of SREBPs in the retina contributes to the fatty acid composition of retinal membranes. The lipid profile of membranes is critical for retinal health and maintenance of the vasculature network. The findings support the rationale to study the role of SREBP transcriptional factors in lipid metabolism in the retina.

ABSTRACT BODY:

Purpose: Keratoconus (KC) is a progressive, vision-threatening disease that is characterized by the thinning and bulging of the cornea. KC is found in both sexes and presents in second decade of life. Extracellular vesicles (EVs) are membranous structures that are shed from the plasma membrane or originate from the endosomal system. EVs transfer information, such as RNA and proteins, from one cell to another. We sought to describe and investigate morphology and biochemical signatures of EVs in tear film isolates from KC patients.

Methods: Tears were collected from 10 healthy (5 males and 5 females) and 9 KC (4 males and 5 females) subjects. Tear samples were collected passively from the lateral meniscus of the eye using a glass capillary tube. Samples were processed and analyzed using the ExoView^{TM} R100.

Results: Analysis demonstrated that KC tears had higher CD9+ and CD63+ than Healthy tears. KC had lower CD81+ than tears from healthy subjects. KC had higher CD81/CD9 colocalization than healthy. KCs had lower CD63/CD9 colocalization than healthy. KCs have lower CD63/81 when compared to healthy. Healthy and KC samples had the same expression of triple colocalization, CD63/CD81/CD9. Sex stratification revealed both KC males/females having higher CD9+ and CD63+ than healthy males/females. KC females had lower CD81+ than healthy females and KC males had a higher CD81+ populations when compared to healthy males. Our data also showed that KC males/females had higher colocalizations of CD81/CD9 when compared to healthy males/females. KC females also showed lower colocalization of CD63/81 than healthy females. KC males had higher colocalization of CD63/CD81 compared to healthy males. KC males/females had lower CD63/CD9 than healthy males/females. KC females had higher CD63/CD81/CD9 than healthy females and KC males had lower CD63/CD81/CD9 than healthy males. Both Healthy and KC derived EVs had a diameter range of 50 to 200nm, with the majority being between 50 and 80 nm suggesting a majority of exosome population and a minor population of apoptotic vesicles.

Conclusions: For the first time, we were able to isolate and characterize tear EVs from KC subjects. The differences described suggest that there is a distinct phenotype present in KC-derived tear EVs when compared to healthy samples. Knowledge of these EV findings may help researchers and clinicians for future diagnosis and management of KC patients.

ABSTRACT BODY:

Purpose: To establish an end-to-end data-driven learning method that detects retinal tasks and image landmarks to determine SLO-based retinal tracking results

Methods: We present a novel method for SLO-based systems to automatically detect eye motion task paradigms and retinal landmarks on image data, such as foveal localization, utilizing a fully data driven, end-to-end DNN based algorithm. Our DNN approaches were tested using a 99-subject concussion/control database collected at the University of Pittsburgh for both fixation and saccade tasks. The task-based detection results aimed to localize the fovea, as well as identify the stimulus target positions of each video sequence to be used for task sorting. These detection results were evaluated and compared with “strip-registration” based approaches to quantify model performance.

Results: Preliminary results of model performances were measured using the IoU (intersection over union) metric by comparing DNN predictions of landmarks on the image with the annotated ground truth. We demonstrate a precision metric of >0.9 and a recall metric of >0.9 for each prediction of certain visual landmarks on the image, which gives an overall mean Average Precision (mAP) >50 for the sorting of retinal motion tasks. This detection approach has a great generalizability for different types of landmark detections following the same supervised training pipeline. We experimented on detecting different types of objects in the image with minimum amounts of training data, on the order of 10 SLO images, by utilizing the concept of “Transfer Learning” with most of the neurons in the DNN pretrained using ImageNet. By doing this, we improved the requirement on training data size and data annotation efforts.

Conclusions: The use of DNN algorithms to extract latent features of SLO videos with supervised training demonstrates exquisite classification and prediction power while alleviating the limitations of manual feature engineering. A generalized data-driven approach to learn the data representation automatically is of the utmost importance to consider the latent features embedded in SLO videos. Future applications of this technique will be applied to quantify saccadic latency to differentiate concussed vs. healthy control subjects.

TITLE: The diurnal relationship of axial length and choroidal thickness in winter and summer.

SESSION TITLE: Myopia and refractive error development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Nilsen, H. Pedersen, L.A. Hagen, J. Stuart, R.C. Baraas, Department of Optometry, Radiography and Lighting Design, Universitetet i Sorost-Norge, Kongsberg, Viken, NORWAY|

Commercial Relationships Disclosure: Nickolai Nilsen: Commercial Relationship: Code N (No Commercial Relationship) | Hilde Rogeberg Pedersen: Commercial Relationship: Code N (No Commercial Relationship) | Lene Hagen: Commercial Relationship: Code N (No Commercial Relationship) | J.Gilson Stuart: Commercial Relationship: Code N (No Commercial Relationship) | Rigmor Baraas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diurnal and seasonal variations in daylight have been implicated in ocular growth (Hagen, Sci. Rep. 2018, 8(1), 1-10.; Ulaganathan, Exp. Eye Res. 2019. 189). The aim of this study was to explore the diurnal relationship between axial length and choroidal thickness in humans in winter and summer at 60° latitude North.

Methods: Twenty-four ocular healthy participants (age 17-24 yrs, 11 males), with logMAR visual acuity ≤0.00 and stereo acuity of ≤120” were included and measured in Southern Norway during the winter (6 hours of daylight/day) and summer (18 hours of daylight/day). On day 1, an actigraph was handed out to the participants to collect habitual sleep times (HST) over a 7-day period. Individual HST and self-reported habitual wake up time were used to calculate the timing of 9 rounds of measurements on day 8. Each round consisted of accommodation washout (15 min), OCT imaging (Heidelberg Spectralis OCT2 EDI) and axial length (AL) measurements (Zeiss IOLMaster 700). The central 1 mm choroid (CT) was segmented with custom-made software using an active-contour method. A sinusoid, with a period of 24 hours, was fit to the data (AL and CT) with an non-linear mixed effects model to estimate the MESOR, amplitude and phase, and determine the seasonal effect of these parameters.

Results: AL ranged from 21.26 to 27.53 mm and CT ranged from 90 to 659 mm. Increasing AL correlated with thinner CT in winter and summer (R^2=0.42, p<0.0001, R^2=0.38, p<0.0001, respectively). AL and CT underwent significant diurnal variations both in winter and summer (one-way ANOVA, p<0.0001). MESOR AL increased significantly from winter to summer (Δ0.045 mm, p<0.0001) whereas MESOR CT did not change. AL and CT acrophase was 12 hours out-of phase in winter and there was a significant acrophase advance for AL only, about 90 min earlier in the summer (p<0.05).

Conclusions: The results show that the diurnal rhythms of AL and CT are in anti-phase in winter, but because there is no evidence for a seasonal change in the diurnal rhythm of CT between winter and summer, we find instead that there is a shift in the relationship between acrophase of AL and CT in summer related to seasonal changes of AL only.

TITLE: Combining OCT Corneal Topography and Thickness Maps to Diagnose Keratoconus Using a Convolutional Neural Network

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Pavlatos, D. Huang, Y. Li, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Elias Pavlatos: Commercial Relationship(s);Code F (Financial Support):Optovue Inc.;Code P (Patent):Optovue Inc. | David Huang: Commercial Relationship(s);Code F (Financial Support):Optovue Inc.;Code P (Patent):Optovue Inc.;Code R (Recipient):Optovue Inc. | Yan Li: Commercial Relationship(s);Code F (Financial Support):Optovue Inc.;Code P (Patent):Optovue Inc.

ABSTRACT BODY:

Purpose: To design a convolutional neural network (CNN) for keratoconus detection using optical coherence tomography (OCT) corneal topography and thickness maps.

Methods: Normal subjects (n = 52) and patients with either keratoconus (n = 131) or contact lens-related warpage (n = 20) were recruited. Keratoconus eyes were divided into 3 groups: 1) Manifest (n = 89): slit-lamp or topographic signs of keratoconus and corrected distance visual acuity (CDVA) < 20/20, 2) Subclinical (n = 16): topographic signs of keratoconus but CDVA ≥ 20/20, and 3) Forme fruste (n = 26): normal-appearing eye with keratoconus in the contralateral eye. The central 6mm of the cornea was imaged using a radial OCT scan pattern (Avanti, Optovue Inc.), and maps of pachymetry, epithelial thickness, anterior surface mean curvature, and posterior surface mean curvature were generated (Li et al, Ophthalmology, 2012; Pavlatos et al, BOE, 2020; Figure 1). All maps were down-sampled to a size of 16×16 pixels. The 4 map types were each treated as different color channels, and a grid search was used to optimize the network architecture and hyperparameters. Binary classification was performed to separate the keratoconus cases and non-keratoconus cases (normal or contact lens warpage). Repeated 5-fold cross-validation was used to evaluate model performance, and class activation maps were generated.

Results: The average balanced accuracy of the CNN during cross-validation was 94 ± 2%. The precision and recall were 98 ± 3% and 91 ± 4%, respectively. The area under the receiver operating characteristic curve was 0.94 ± 0.02. The network was able to detect 100% of the manifest and subclinical keratoconus cases. The accuracy for the forme fruste keratoconus cases was 56 ± 19%. The network demonstrated good specificity, with 97 ± 6% of normal eyes and 96 ± 9% of warpage eyes being classified as non-keratoconus cases. The class activation maps indicated that the regions of the topography and thickness maps which contained the keratoconic cone were most important to the CNN for disease detection (Figure 2).

Conclusions: OCT mapping of the cornea and CNNs can be used to detect keratoconus with high accuracy. This approach could be expanded to automate the classification of corneal diseases.

ABSTRACT BODY:

Purpose: Macular telangiectasia type II (MacTel) is a macular degenerative disease that causes progressive vision loss. While MacTel is predominantly characterized by macular defects, post-mortem eye studies in MacTel patients reveal pan-retinal changes in the retinal pigmented epithelium (RPE), including reduced phagosomes compared to age-matched controls. We have reported that MacTel patients exhibit low circulating levels of serine and glycine. The impact of these non-essential amino acids on RPE function is unknown. The purpose of this study was to assess the impact of reduced serine and glycine on RPE phagocytic function.

Methods: To assess RPE phagocytic function, we cultured human fetal RPE cells in serine- and glycine-free media, measured expression of endosomal markers, and quantified phagocytic capacity via flow cytometry and imaging. To assess the impact of reduced circulating serine and glycine levels on RPE in vivo we aged mice on a serine- and glycine-free diet and quantified RPE phagosomes using electron microscopy.

Results: We found decreased phagocytic function in human fetal RPE cells after culture in serine- and glycine-free media. Interestingly, these cells also had elevated expression of endosomal markers. Mice aged on a serine and glycine-free diet had fewer phagosomes in their RPE, recapitulating what was observed in MacTel patients.

Conclusions: RPE phagocytic capacity is disrupted when serine and glycine availability is reduced, both in vitro and in vivo. This suggests that the reduced levels of circulating serine and glycine observed in MacTel patients may be a contributing factor to RPE dysfunction and macular disease.

TITLE: Effect of Bimatoprost Treatment on Lymphangiogenesis in Human Ciliary Body Smooth Muscle Cells

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Boehm, Case Western Reserve University School of Medicine, Cleveland, Ohio, UNITED STATES|D. Rhee, Ophthalmology, UH Cleveland Medical Center, Cleveland, Ohio, UNITED STATES|A. Gidh, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Blake Boehm: Commercial Relationship: Code N (No Commercial Relationship) | Anoushka Gidh: Commercial Relationship: Code N (No Commercial Relationship) | Douglas Rhee: Commercial Relationship(s);Code C (Consultant/Contractor):Allergan

ABSTRACT BODY:

Purpose: The presence of uveolymphatic pathways were recently discovered and may contribute to drainage of aqueous humor and regulation of intraocular pressure (IOP). Bimatoprost is a prostaglandin-analog commonly used to reduce IOP. Prior work with topical bimatoprost in monkey demonstrated partially endothelial lined passages within the ciliary body stroma. We hypothesized that these passages are lymphatic in nature and human ciliary body smooth muscle (CBSM) cells are the source of the lymphangiogenic proteins.

Methods: CBSM cells were dissected and cultured from the anterior segment of four human donors ages 60, 62, 73, and 76. CBSM cells were treated with vehicle control (0.001% ethanol), 3.3, 10, 25.7, or 257 nM of bimatoprost or bimatoprost free acid. Immunoblot analysis was performed on cell lysates to determine the effect of drug treatment on protein expression for the lymphatic markers: LYVE-1, PROX-1, TIE-1, ANG-1, ANG-2, and NRP-2. Fold-change as compared to vehicle control was quantified and two-tailed paired t-tests were used for statistical analysis.

Results: Bimatoprost treated CBSM cells demonstrated a 33 ± 7% decrease in NRP-2 expression (n=3; p=0.048) at 10 nM, while no dose-dependent trend was observed for LYVE-1 (n=2), TIE-1 (n=3), or PROX-1 (n=3). ANG-1 (n=2) and ANG-2 (n=1) exhibited a dose-dependent although non-statistically significant increase in protein expression with a maximal increase of 56% and 64% for ANG-1 and ANG-2, respectively. Bimatoprost free acid treated CBSM cells (n=1 for each target) exhibited a dose-dependent decrease in NRP-2, no dose-dependent trend in LYVE-1, PROX-1, or ANG-2, and a dose-dependent increasing trend in TIE-1 and ANG-1.

Conclusions: Our study confirmed the expression of lymphatic markers by human CBSM cells, and that bimatoprost and bimatoprost free acid had differential effects on lymphatic gene expression in CBSM. The significant decrease in NRP-2 at 10 nM of bimatoprost may be due to changes in receptor trafficking since NRP-2 is a co-receptor for VEGFR-3. Increases in TIE-1, ANG-1 and ANG-2 may indicate development of lymphatics in response to drug treatment. Experiments are ongoing to better characterize this trend.

TITLE: Investigating the effects of RPE detachment on angiogenic factors using micropatterning

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Paterson, J. Cannon, E. Vargis, Biological Engineering, Utah State University, Logan, Utah, UNITED STATES|

Commercial Relationships Disclosure: Chase Paterson: Commercial Relationship: Code N (No Commercial Relationship) | Jamen Cannon: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Vargis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During age-related macular degeneration (AMD), RPE cell detachment can cause overexpression of proangiogenic factors, such as vascular endothelial growth factor (VEGF). The only approved treatments target VEGF to slow angiogenesis progression in AMD. However, other angiogenic proteins may also be viable targets. Clarifying the relationship between RPE cell detachment and other angiogenic factor secretions could lead to more therapeutics and increase the efficacy of current treatments. Understanding this relationship is difficult with current methods, such as animal models or scratching assays, as they can be costly, time-consuming, or nonrepresentative.

Methods: To better model RPE cell detachment, we use a method called micropatterning to control the spatial arrangement of cells by preventing growth using polydimethylsiloxane stencils. AutoCAD software was used to generate patterns, which were then formed into stencils to mimic 10, 25, and 50% overall detachment of an RPE monolayer. These increasing amounts of detachment correspond to AMD progression. After the stencil areas were verified by comparison to the original CAD drawings, the growth of primary porcine RPE cells was successfully controlled using stencils. Trypan blue exclusion assays were used for cell counts, which were used in an enzyme-linked immunosorbent assay to correlate amounts of angiogenic secretion to levels of RPE detachment.

Results: Morphological changes were seen with a decrease in pigmentation, showing a decline in barrier and light absorption functions as degeneration increased. One day after stencil removal, the degree of change of angiogenic factor secretions correlated to level of detachment. Whereas VEGF concentration was not as affected by varying levels of detachment as anticipated, intriguingly, angiopoietin-2 secretion had some of the most noticeable changes.

Conclusions: Engineering methods can be used to create tunable models of RPE cell-cell detachment and degeneration correlated to AMD pathologies. Angiogenic factor secretion was affected by varying levels of detachment. Immunocytochemical staining and a phagocytosis assay will be used to visualize angiogenic protein expression and see how other crucial functions are affected by detachment. The results of this research will clarify how different levels of degeneration can impact the expression of angiogenic proteins and possibly reveal other therapeutic targets.

ABSTRACT BODY:

Purpose: DED is characterized by ocular irritation and potential visual impairment due to inflammation and tear deficiency. Melanocortin agonists may represent a new therapeutic avenue to treat inflammatory ocular diseases. The efficacy and tolerability of the melanocortin receptor pan-agonist PL9643 was examined in a subpopulation of subjects with moderate to severe DED as part of a phase 2 study.

Methods: This was a randomized, placebo-controlled study of subjects with DED. A subpopulation of subjects (n=53) with a duration of DED≥5 years, inferior corneal staining>1, and eye discomfort on a visual analog scale (VAS)≥25 was analyzed. Subjects received placebo solution during a 2-week run-in period and were randomized to either placebo or PL9643 topical solution TID for 12 weeks. The controlled adverse environment (CAE™) model was used to exacerbate signs/symptoms. Endpoints included TFBUT, changes in inferior corneal fluorescein staining and ocular discomfort (Ora Calibra® scales) after 2 and 12 weeks. Other endpoints were changes in additional signs/symptoms of DED, and occurrence of adverse events (AEs).

Results: In these subjects with moderate or severe disease (n=53), PL9643 treatment demonstrated a significant improvement over placebo at week 12 for TFBUT with an LS means treatment difference vs placebo of +0.4058 (P=0.0137). PL9643 treatment also demonstrated a significant improvement over placebo for fluorescein staining with treatment differences of -0.55 (P=0.0097) for inferior corneal staining and -0.93 (P=0.0242) for corneal sum staining (inferior, superior, and central). Ocular discomfort demonstrated significant improvement vs placebo in change from baseline at week 2 (treatment difference -0.4, P=0.0227). In addition, PL9643 treatment demonstrated numerical improvement in conjunctival redness (Ora Calibra® scale) and in VAS symptoms at weeks 2 and 12. Fewer AEs occurred in those receiving PL9643 vs placebo and there were no treatment-related serious or ocular AEs observed.

Conclusions: In subjects with moderate or severe DED, PL9643 led to significant improvement in TFBUT at week 12 and other subjective and objective benefits at 2 weeks which were maintained for 12 weeks vs placebo. PL9643 had a safety profile comparable to placebo. Results support the continued development of PL9643 as a novel therapeutic method for DED.

ABSTRACT BODY:

Purpose: There is no cure for primary open-angle glaucoma (POAG), characterized by progressive optic nerve damage and vision loss, due to limited understanding of the molecular and cellular causes. Here we aimed to identify genes and cell types that may affect POAG risk by integrating known POAG and intraocular pressure (IOP) genetic loci with genetic regulation of gene expression (eQTLs) and splicing (sQTLs), and single cell expression in ocular tissues.

Methods: We developed a method called ECLIPSER, that tests whether expression of genes mapped to genome-wide association study (GWAS) loci of a complex trait, based on e/sQTLs, is enriched in specific cell types. For each trait, tissue, and cell type, a GWAS locus is scored based on the fraction of cell type-specific genes (fold-change>1.3, FDR<0.1). Cell type enrichment of a GWAS loci set is assessed against a null distribution of loci of unrelated traits taken from Open Target Genetics, using a Bayesian Fisher's exact test. We mapped genes to 127 POAG loci and 133 IOP loci found in large GWAS meta-analyses, by applying colocalization methods, eCAVIAR and enloc, to the GWAS loci and overlapping e/sQTLs from 49 GTEx tissues and retina eQTLs (EyeGEx). GeneEnrich was used for gene set enrichment in biological processes.

Results: ≥1 e/sQTL colocalized with 61% (202 loci) of POAG and IOP GWAS loci (Posterior Prob>0.01), with an average of 3-4 genes per locus. POAG genes were enriched in elastic fiber formation and extracellular matrix organization (P<6E-05, FDR<0.01), and IOP genes in vasculature development (P=5E-05, FDR=0.13). Applying ECLIPSER to the mapped genes and single-nucleus RNA-seq of the anterior segment (AS), optic nerve head (ONH) and retina from healthy eyes, identified significant enrichment (P=0.01-4E-04, FDR=0.008-0.16) for POAG in astrocyte and Müller glia in ONH and retina, and ciliary and iris fibroblasts in the aqueous outflow pathway in AS. The IOP genes were enriched in smooth muscle, astrocyte, pericyte, and vascular endothelium in ONH, astrocyte in retina, and trabecular meshwork and ciliary fibroblasts in AS (P=0.001-0.009, FDR=0.02-0.15).

Conclusions: This work suggests hundreds of regulatory mechanisms and genes that may contribute to POAG risk in specific cell types in the front and back of the eye, which could help guide novel therapies.

ABSTRACT BODY:

Purpose: Visual prosthesis wearers' ability to locate people and objects in real-life environments is limited by low resolution and distracting information. Object recognition by a neural net can assist them, provided we can efficiently convey information about the location and nature of a desired object in the visual field.

Methods: Video from a head-worn camera was analyzed for the presence of selected objects by a TensorFlow SSD neural net trained on the COCO dataset, running on a Raspberry Pi processor in a control box worn by the subject. Subjects wore their Argus system and earbuds, and were either shown the raw Argus II video or given one of 3 prompts for objects in view: a flashing icon in the image, icon + binaural tone conveying direction and size/closeness, or icon + spoken object identity. Here we present data collected in Argus II users looking for and walking towards a person in our lab in one of 6 pre-selected random positions. Each position was tested twice, in random order, followed by a return trial to the starting location; a trial ended in reaching the target or time-out/incomplete. Prior to testing, subjects familiarized themselves with the size of the room and were given several practice trials on a person standing nearby, with each modality. Outcomes were success rate, number of steps, and time to completion.

Results: With the native Argus II system, success rates varied from 25–38%; 95–99 s and 27–33 steps were required to reach the target. In the trials with prompts, these values were: 92 – 96%, 26–34 s and 9–17 steps (icon); 83 – 100%, 31–32 s and 12–15 steps (icon+tone); and 92 – 100%, 35–37 s and 9–18 steps (icon+voice). All changes in prompted trials relative to the native system were significant by 2-tailed t-test. Only for one subject was a difference found between prompts: Icon + tone resulted in faster completion than icon alone. Return trials showed a slight, but not significant, improvement over outbound trials. Subjects preferred using the system, but did not express a preference for a particular prompt.

Conclusions: Providing an Argus II user with a system that detects a desired object results in significant improvement of all measured performance aspects, but no evidence was found for advantage of a particular alert system.

ABSTRACT BODY:

Purpose: The eye is one of the most sensitive organs to toxic chemical exposures. Ocular chemical injuries cause corneal damage and the loss of viable corneal epithelial cells, leaving patients with few effective treatment options. Nitrogen mustard (NM), a structural analog of warfare agent sulfur mustard, is a vesicating agent. Chloropicrin (CP), is a broad-spectrum pesticide that is used in agriculture, and is also a warfare agent. NM and CP can have severe toxic effects to the eye including irritation, corneal edema, and long-term ocular injuries but there are no effective therapies available. Our previous studies indicate that eye toxicity from NM and CP exposure can cause activation of signaling pathways related to DNA damage, oxidative stress, and inflammation. Triterpenoids are activators of the nuclear factor-erythroid factor 2-related factor 2 (Nrf2) pathway, which transcriptionally activates genes related to anti-inflammatory responses and cytoprotective effects reducing oxidative stress. Thus, activating Nrf2 pathway can be a targeted approach for the treatment of chemical induced corneal toxicity.

Methods: Human corneal epithelial (HCE) cells were exposed to 60 μM NM for 6 or 24 hours. mRNA was isolated and qPCR analyses were carried out for Nrf2 pathway related genes, inflammatory markers, and cytokines.

Results: NM exposure led to a decrease in Nrf2 mRNA expression at 24h post exposure. Changes in phase II antioxidant enzymes of the Nrf2 pathway NAD(P)H quinone dehydrogenase-1 (NQO-1) and heme oxygenase-1 (HO-1) were observed. NQO-1 mRNA expression decreased at both 6 and 24h post NM-exposure, while HO-1 expression increased at 6h (6.5-fold increase) followed by a decrease at 24 h. NM exposure caused a decrease in the mRNA expression of antioxidant enzymes catalase and glutathione peroxidase-1 at both the time points. An increase in TNF-α mRNA expression (1.8-fold) was observed at 24h post NM exposure.

Conclusions: NM exposure in HCE cells causes increased expression of inflammation, and oxidative stress related markers and decreases the expression of Nrf2 pathway genes. Since CP has similar effects to the vesicating agent NM, we are investigating the involvement of the Nrf2 pathway in CP-induced corneal injury in HCE cells. Based on these studies, we will further evaluate the effect of activating Nrf2 pathway by triterpenoids for the treatment of NM and CP-induced corneal toxicity.

ABSTRACT BODY:

Purpose: Polygenic predisposition to advanced age-related macular degeneration (AMD) enables strategies to define the complex pathogenesis of this disease. We combined human genetics and in vivo functional studies in Drosophila melanogaster to identify novel pathways implicated in AMD pathogenesis.

Methods: Whole genome sequencing (WGS) and subsequent rare variant (RV) burden test analyses were performed for 6055 advanced AMD cases and 8294 non-AMD diseased controls. We extracted rare exonic SNPs (minor allele frequency <1%) predicted to alter amino acids or affect functionality of the protein. Since comparison cohorts were comprised of non-AMD clinical trial patients, a reverse regression with a Bayesian spike and slab prior was used to remove non-AMD specific associations. For functional characterization of candidate genes at association signals, we performed RNAi screens using Drosophila models. The impact of whole eye knockdowns of orthologous genes of interest on photoreceptor survival was assessed using deep pseudopupil (DPP) and optic neutralization of cornea imaging approaches that follow ommatidial morphology.

Results: WGS for RV burden tests pinpointed multiple genes, including the top hits CFI (P=3.13E-14; OR=4.57), CFH (P=2.14E-06; OR=2.05), and SLC16A8 (P=1.50E-05; OR=1.78), all from loci previously associated with AMD (Table 1). We focused functional analysis on the proton-coupled monocarboxylate transporter SLC16A8 (solute carrier family 16 member 8) which is expressed only in the retinal pigment epithelia of humans and also rodents. Knockdown of the Drosophila ortholog sln (silnoon) led to progressive loss of retinal homeostasis in the adult fly, as visualized by changes in photoreceptor EGFP expression patterns at day 14 (95% mean loss of DPP), but not by day 1, 7, or in comparison to negative controls (n=10 for each line and timepoint; reproduced in two separate assays).

Conclusions: An unbiased, genome-wide analysis of rare coding variants provided additional support of a causal role for SLC16A8 in protection against AMD when functional. We demonstrate that deletion of the Drosophila ortholog sln disrupts retinal homeostasis, and highlight a potential therapeutic opportunity for the treatment of AMD.

ABSTRACT BODY:

Purpose: The fact that diabetic retinopathy (DR) typically takes decades to develop suggests the existence of an endogenous system that protects from diabetes-induced damage. The purpose of this project was to consider if such a system is present in primary human retinal endothelial cells (HRECs).

Methods: HRECs were cultured in endothelial cell-specific media from Lonza containing 5 mM (normal glucose, NG) or 30 mM D-glucose (high glucose, HG). Expression of VCAM1 protein was evaluated by Western blotting. Cell death was measured by Annexin V and propidium iodide staining. Mitochondria functionality was assessed by oximetry (Seahorse analysis of basal respiration, spare respiratory capacity, and the level of ATP) and a novel approach measuring resolution of an acute increase in reactive oxygen species. A fluorescent probe, mtKeima, was used to monitor mitophagy. Mitophagy was suppressed by siRNA-based approaches to reduce the expression of genes required for mitophagy. Endothelial cell barrier integrity was monitored via trans-endothelial electrical resistance (TEER). Two-tailed Student's t-test was used for statistical analysis.

Results: We expected that HG would be deleterious to HRECs, and that prolonging the exposure would increase damage. Instead, we observed that extended exposure to HG was beneficial. While TNFa-induced expression of VCAM1 was similar in HG versus NG after a short exposure to HG, it became lower in HG cells if the exposure to HG was extended. Similarly, oxidative stress-induced death declined in HG cells as the duration of exposure to HG was prolonged. Furthermore, mitochondrial functionality, which was compromised by 1 day of HG, improved in cells that were cultured in HG for 10 days. Prolonged exposure to HG increased clearance of damaged mitochondria (mitophagy), which provides a mechanistic explanation for how HG improved mitochondrial functionality. Finally, antagonizing mitophagy compromised the cells' ability to endure HG; susceptibility to cell death increased and barrier function declined.

Conclusions: HG induces adaptation of HRECs, which enables them to resist cytokine-induced activation and oxidative stress-induced death. The underlying mechanism involves enhanced mitophagy leading to increased mitochondrial functionality. Hyperglycemia-induced mitochondrial adaptation (HIMA) exists in HRECs and is a plausible explanation for the delayed onset of DR.

ABSTRACT BODY:
Purpose: The primary hyperoxalurias (PH; PH1-3) are three rare inherited disorders of the glyoxylate metabolism characterized by endogenous overproduction of oxalate. As oxalate cannot be metabolized by humans, PH may affect various organs, most notably the kidneys, bones, heart, and eyes. Vision loss and severe oxalate deposition are commonly seen in infantile PH1, whereas non-infantile PH1 usually present with no or mild retinal alterations. If patients with PH2 and PH3 develop retinal disease has not been investigated so far. This is, however, important in light of emerging therapeutic options. Here, the ocular phenotype in patients with PH2 and PH3 and its relation to systemic disease is investigated.
Methods: A renal, molecular and ophthalmic examination including multimodal retinal imaging (OCT, fundus autofluorescence imaging, fundus photography) was performed of each patient.
Results: Thirteen patients (4 with PH2; 9 with PH3) from 11 families were included. Median age at first renal symptoms and diagnosis was 1.5 and 4.5 years in PH2 patients; and 3 and 7 years in PH3 patients. Median age at time of ophthalmic examination was 11 years and median BCVA was 20/20. A 30-years-old patient with PH2 had drusen-like deposits in both eyes that were interpreted as crystallized oxalate. On OCT imaging, these deposits appeared as focal hyperreflective subretinal lesions. At the time of the ophthalmic examination, he was on dialysis and his oxalate level was markedly elevated. The remaining 12 patients showed no retinal oxalate deposits. Out of those 12, only the oldest PH2 patient (59-years-old) had elevated oxalate levels and end-stage kidney failure (ESKF), whereas all other PH2 and PH3 patients had had normal or near-normal plasma oxalate levels.
Conclusions: Retinal disease manifestation in PH2 and PH3 clearly differs from patients with infantile PH1. Age of ESKF-onset might be an important predictor for retinal alterations in PH. A later decline in kidney function associated with increased plasma oxalate levels could also increase the risk of systemic oxalosis with subretinal oxalate deposition. At this mild end of the phenotypic spectrum, additional genetic and/or environmental modifiers might result in variable susceptibility.

ABSTRACT BODY:

Purpose: We performed scRNA-sequencing of human donor corneas and cornea organoids derived from induced pluripotent stem cells (iPSC) and matured in culture for 4 months to elucidate the transcriptomic cell fate of human cornea organoids.

Methods: Three cornea organoids and 3 healthy donor corneas (Lions Eye Institute for Transplant and Research, FL) were digested with collagenase to prepare single cell suspension. Libraries were generated using Chromium Single Cell 3' Library & Gel Bead Kit v2 (10x Genomics). The libraries were run on an Illumina HiSeq 4000 as 150-bp paired-end reads. The Cell Ranger Single-Cell Software Suite v3.01 was used to perform sample demultiplexing, barcode processing, and quality control filtering and integrating. The integrated dataset has 55,241 cells in the gene-cell-barcode matrix that includes a total 25,885 and 29,356 cells from the 3 organoids and 3 human corneas, respectively.

Results: The transcriptomic data showed high reproducibility within each sample category. Differential gene expression analysis between the two sample categories showed 559 genes to be uniquely expressed in the organoid, 389 in the cornea and 971 genes expressed in common. An integrated analysis of the corneas and the organoids yielded 30 distinct cell clusters (CL). Of these, 14 CL were detected in the cornea and 10 in the organoid samples (Fig.1). The organoids harbor cell clusters representing corneal epithelium (KRT5), stroma (LUM) and endothelium (TJP1) with minor population of myofibroblast-like cells (5%) and immune cells (CCL3). Unlike the cornea, where the largest group consists of stromal cells, the organoid shows almost equal proportion of epithelial (28%), stromal (33%) and endothelial (31%) cell contribution. Interestingly, we also found the organoid cell fates to be consistent with that of a developing cornea that shows high expression of SIX3 and PAX6. The organoids also have low expression of KERA, KRT12, ALDH3A1 and KLF4, known to be expressed in the adult cornea.

Conclusions: Our work, provides for the first time, a transcriptomic map of human cornea organoids at a single cell resolution. The organoids recapitulate epithelial, endothelial and stromal cell fates of the developing cornea. These well characterized organoids offer a 3D platform to investigate corneal development, diseases and cell-based therapies.

ABSTRACT BODY:

Purpose: Older adults with combined hearing and vision loss (dual sensory loss/DSL) are a highly vulnerable population during the COVID-19 pandemic. Although around 1.1 million older Canadians live with DSL, data are scarce on how COVID-19 affected their access to healthcare during the pandemic. Therefore, the present study explored the impact of COVID-19 on healthcare access for older Canadians with DSL.

Methods: We distributed an online survey for healthcare workers who provided services to older adults with DSL during the pandemic. Survey data were collected from 228 Canadian healthcare workers between August and November 2021. Content analysis was used to analyze open-ended qualitative data, whereas descriptive statistics were used for quantitative survey data using SPSS.

Results: Almost all healthcare workers felt that COVID-19 has negatively affected their care delivery to older adults with DSL, especially due to physical distancing and use of Personal Protective Equipment. Moreover, those using telehealth with their older clients reported that COVID-19 related shift to telehealth appointments restricted access to healthcare for their clients. Most respondents (91%) felt that older adults with DSL found it difficult to follow pandemic-related physical distancing guidelines in a clinical or health system setting. While 69% of them believed that the health system was not adapted to match the needs of older adults living DSL, 71 % felt healthcare professionals are not adequately trained to meet the needs of this population in pandemic situations such as COVID-19.

Conclusions: We concluded that the pandemic has negatively impacted healthcare services to older adults with DSL. The pandemic accentuated the need for equitable care for older adults with DSL, considering the unique challenges experienced by them and their healthcare providers. Our study findings underscored the need for training of healthcare professionals on the communication and accessibility needs of older adults living with DSL.

ABSTRACT BODY:

Purpose: Generation of retinal organoids (RO) from conventional, primed hPSCs is inefficient and optimized in only a few ‘permissive’ lines. We recently established naïve epiblast-like TIRN-hPSC with reduced interline variability of differentiation for improved vascular progenitor engraftment. Here, we tested whether TIRN-hPSC-derived ROs also possess improved in vivo development to mature photoreceptors.

Methods: Isogenic primed vs TIRN-hPSC were differentiated with an established 3D RO protocol. Horse-shoe (HS)-shaped domains matured to retinal cups (RC) with laminated layers. Neuroepithelial specification and epigenomic integrity were validated at 4-20 weeks by RT-PCR, immunofluorescence, RNA-Seq, and CpG methylation sequencing. Interline variability of RC differentiation was quantitated to 16 weeks. RC neural sheets were transplanted into the subretinal space of NOG-SCID mice, and human photoreceptor specification and engraftment was evaluated at 6-9 months post-transplant.

Results: Although several conventional hPSC lines failed to differentiate into RCs, all TIRN-reverted hPSC efficiently generated HS domains and well-differentiated RC organoids with efficiencies comparable to “permissive” hPSC lines. Eye field-specific transcripts and photoreceptor progenitor markers (2-20 weeks) were detected in greater quantities in TIRN RCs (e.g., CRX^+RCV^+, HuC/D^+ ganglion/amacrine cells, $PROX1^+$ horizontal cells, $MITF^+$ pigmented epithelium). TIRN-derived RO displayed improved maturation of $rhodopsin^+$ photoreceptors with proper histo-architecture. Confocal microscopic evaluation of NOG eyes transplanted with TIRN-derived RC sheets demonstrated long-term engraftment (10 months) of mature human cells in tabulation-like structures with development of a full repertoire of mature rod/cone photoreceptors (e.g., $rhodopsin^+$, L/M $opsin^+$, $recoverin^+$), astrocytes ($GFAP^+vimentin^-$), and Mueller cells ($GFAP^+vimentin^+$). Transcriptomic and epigenetic studies revealed that chemical PARP inhibition of the TIRN method mediated the improved epigenetic plasticity to retinal lineages.

Conclusions: TIRN reversion of conventional hPSCs abolished interline variability of RO development across genetic background, augmented retinal fate specification, and potentiated long-term survival of transplanted photoreceptors for at least 10 months.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic led to disrupted corneal supply to countries tributary to foreign eye bank donations. The authors carried out the first retrospective, observational study to assess the impact of the pandemic on corneal tissue supply and quality in Morocco, by comparing the surgical patterns during the pre-pandemic time and the first year of the pandemic at the only tertiary eye center performing keratoplasty in Morocco.

Methods: A retrospective analysis comparing the years 2019 and 2020 (January 1^{st} to December 31^{st}) was performed based on electronic health records database from the department of Ophthalmology at Cheikh Zaid International Hospital.Quantitative analysis evaluated the numbers of keratoplasties performed, the number procedures for therapeutic or tectonic purposes, the numbers of delivered corneal tissue, numbers of patients on the waiting list. Quality assessment of the grafts was based on the mean endothelial cell density count provided by the supplier, prior to corneal surgery. The comparison was based on a Chi2 test with $p<0.05$ considered statistically significant. Statistical study was performed using Jamovi (The Jamovi project2021,Version 1.6[Computer Software])

Results: Out of a total of 345 patients registered on the corneal transplant list on 2019, 252 patients underwent keratoplasty (73%) with 4,4 % for tectonic or therapeutic purposes, whereas out of 507 patients on the list on 2020, 160 received keratoplasty (31,55%) with 13,7% in a context of emergency. The waiting list grew from 293 patients in 2019 to 453 in 2020 marking an increase of 21,4 %. A statistically significant decrease in the number of corneal tissue received at our center was noted, with a mean of 4,8 (+/- 4,23) per week in 2019 and 2,9 (+/- 3,02) per week in 2020 (p=0,02).All corneal tissue was exclusively provided by three US eye banks. Mean endothelial cell density count prior to surgery was not statistically different between 2019 (2699 c/mm^3 +- 255) and 2020 (2668 c/mm^3 266),(p= 0,22).

Conclusions: These results reflect the imbalance between corneal demand and supply creating a disruption of the corneal tissue chain in Morocco. Given the exceptional activity of the local Eye bank of Morocco due to numerous challenges, and the scarcity of centers that perform keratoplasty, Morocco witnesses a gap between corneal blindness and access to keratoplasty which was further enlarged during the pandemic.

ABSTRACT BODY:

Purpose: Retinal degeneration is a common cause of vision loss, and photoreceptor loss is specifically involved in blinding diseases such as age-related macular degeneration and retinitis pigmentosa. Finding an oral agent that prevents retinal degeneration is an ideal goal for treating these diseases. The purpose of this study is to evaluate the efficacy of an oral purine metabolite as a retina protective agent in two rodent models: aged Fischer344 rats and $Rho^{P23H/+}$ knock-in mice.

Methods: Aged Fischer344 rats were treated with the purine compound by supplementing the agent at 5 mg/kg in drinking water. Treatment began at 22 months of age and lasted for 8 weeks. Electroretinogram (ERG) and optical coherence tomography (OCT) were recorded at 0 and 7 weeks of treatment. Retinae were collected at 8 weeks of treatment for purine analyses, RNA-seq, immunoblots, and immunohistochemistry. Non-treated age-matched animals were used as controls. $Rho^{P23H/+}$ mice were treated with 11 mg/kg of the purine metabolite beginning at postnatal day (PND) 15 by daily intraperitoneal (i.p.) injections. Drinking water for the mother of the treated litter, and subsequently the weaned pups, was also supplemented with the agent. Retinal morphology and function were evaluated weekly by ERG and OCT until the mice were sacrificed at 5 and 7 weeks of treatment. Mice treated with PBS by i. p. injections were used as vehicle controls.

Results: Eight weeks of daily oral treatment by a purine metabolite led to potent retinal protection in the Fischer344 rats at 2 years of age. This was demonstrated by thicker retinae and outer segment layers, and a higher number of nuclei in outer nuclear layer and retinal ganglion layer. Higher scotopic ERG responses were observed, suggesting improved retinal function. Rhodopsin level was significantly increased by the treatment, suggesting restored rod photoreceptor homeostasis. Systemic treatment with the same agent in $Rho^{P23H/+}$ mice also showed delayed retinal degeneration and improved retinal function via OCT and ERG, respectively.

Conclusions: We discovered an oral agent that potently protects the retina against degeneration in two rodent models, thus providing a promising direction for drug development against retinal dystrophies.

ABSTRACT BODY:

Purpose: A variety of conditioning treatments share a strong preclinical track record for epigenetically modifying the retina in ways that protect it from injury and disease [1]. Translational relevance is enhanced by the demonstration that repetitive conditioning can extend the disease-resilient phenotype long after treatment [2-4]. In the present study, we performed quantitative mass spectrometry (MS) on retinae from male and female mice following 2 wks of repetitive hypoxic conditioning (RHC) to gain a proteome-wide understanding of the epigenetically modified phenotype induced prior to injury.

Methods: Adult, outbred Swiss-Webster ND4 mice of both sexes were treated with RHC, or served as normoxic controls; whole retinae (without choroid/RPE) were harvested the following week and processed for MS3 analysis on a Fusion Orbitrap MS using TMTpro labels for quantification, with <5% FDR. Differentially expressed proteins (>1.1 fold-change) were analyzed bioinformatically (z-score>2) (IPA, Qiagen).

Results: MS identified and quantified 6253 proteins, 688 of which were differentially expressed in response to RHC across both sexes. The expression of 166 of these proteins changed uniquely in males or females, whereas that of 522 proteins (216 upregulated and 306 downregulated) were sex-independent. Findings in the latter group implicated increased nuclear (MAF, SOX17, TP53, WT1) and mitochondrial (TFB1M, PHB) transcription, enhanced blood-retinal barrier integrity (PTGDS, MAPK7), increased ceramide synthesis (SMPD1), and Akt/mTOR activation (PIP4P1, KRT17). Bioinformatic analyses of these shared proteins predicted RHC-induced changes in the expression of proteins involved in diverse signaling and metabolic pathways consistent with the promotion of cell survival/anti-apoptotic signaling and free radical scavenging, and a reduction in inflammation, microglial reactivity, microtubule dynamics, and cell migration/movement.

Conclusions: RHC induces widespread and sustained changes in the retinal proteome prior to injury/disease. This 'prime-the-pump' phenotype, conserved across sexes, is foundational to understanding innate, epigenetically-induced mechanisms of neuroprotection that could be leveraged for therapeutics.

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) apoptosis is the common endpoint in glaucoma and both the intrinsic and extrinsic apoptotic pathways have been implicated in human and experimental models of glaucoma. However, caspase 8, which is central to the extrinsic pathway of apoptosis has been linked to both RGC apoptosis, as well as glial activation, and neuroinflammation. The recent development of a caspase 8 mutant mouse ($Casp8^{DA/DA}$) in which a point mutation in the auto-cleavage site blocks caspase 8-mediated apoptosis but does not block caspase 8-mediated inflammation, allows us to uncouple the two pathways and determine the extent to which caspase 8-mediated inflammation and/or apoptosis contributes to the death of RGCs in glaucoma.

Methods: Intracameral injection of magnetic microbeads (control: saline) was used to elevate the intraocular pressure (IOP) in three groups of mice: WT mice (positive control, RGC apoptosis); Fas deficient Fas^{lpr} mice (negative control, no RGC apoptosis); $Casp8^{DA/DA}$ mutant mice (experimental, no extrinsic apoptosis). IOP was monitored by rebound tonometry. At 5 weeks post microbead injection, visual acuity was measured by optomotor reflex (OMR) and RGC function was assessed by pattern ERG (pERG). Retina and optic nerves were processed for RGC and axon quantification.

Results: Rebound tonometry showed equal elevation of IOP in microbead-injected WT, Fas^{lpr}, and $Casp8^{DA/DA}$ mice as compared to saline controls. At 5 weeks post microbead injection, as compared to saline controls, a significant reduction in both visual acuity and pERG was observed in WT mice (pos. control), which correlated with a significant loss of RGCs and axons. By contrast, no significant reduction in visual acuity or pERG, nor loss of RGCs and axons was observed in Fas^{lpr} mice (neg. control). The $Casp8^{DA/DA}$ mice, in which the extrinsic apoptotic pathway is blocked, displayed a significant reduction in visual acuity and pERG equal to that observed in WT mice and, as in WT mice, this loss of function correlated with a significant loss of RGCs and axons.

Conclusions: Our data shows that the caspase 8-mediated extrinsic pathway of apoptosis is not required for the death of RGCs and loss of visual function in a microbead-induced mouse model of glaucoma, indicating that caspase 8-mediated inflammation, but not apoptosis is the driving force in the development of glaucoma.

ABSTRACT BODY:

Purpose: The relationship between placental inflammation and retinopathy of prematurity (ROP) is debated. Clarity may provide clues to potential pathomechanisms influencing pre-clinical ROP risk.

Methods: Acute placental inflammation for infants born prior to 32 weeks between 2010-2019 at one institution was characterized using gold-standard Amsterdam histology grading criteria denoting acute maternal versus infant-level inflammation. Relationships between histology, presence or absence of ROP, gestational age (GA), sex and birthweight (BW) were determined by univariate and multivariate analysis; infants were excluded if full clinical data were not available. In parallel, candidate ROP proteins were measured in cord blood specimens from a prospectively collected validation cohort of infants born prior to 31 weeks with (n=11) or without (n=12) acute placental inflammation using ELISA (HTRA1 and IGF1) or Luminex (VEGFA and TGFb-1). Protein values were correlated with histology outcomes using a one-tailed t-test.

Results: 182 infants met inclusion and exclusion criteria; 100 infants demonstrated presence of ROP. Univariate analysis demonstrated significantly positive correlations (p£0.1) between the presence of ROP, BW (p= 5.48e-09) and GA (p=6.56e-12); significant inverse correlations were identified between preeclampsia (p=0.03) and acute histologic placental inflammation (p=0.09). In multivariate analysis GA remained positively correlated with ROP (p=5.34e-09) and acute inflammation inversely correlated (p=0.02). BW and preeclampsia did not remain significant. Further analysis of placental inflammation by severity revealed significant inverse associations for both maternal-level (p=0.01) and infant-level (p=0.005) inflammation with the presence of ROP disease. Candidate proteins HTRA1 (p=0.003) and TGFb-1 (p=0.02) were significantly increased in cord blood from infants born in the setting of acute placental inflammation histology compared to non-inflammatory placental histology. Changes in VEGFA and IGF1 were not significantly associated with ROP development.

Conclusions: Utilizing a systems biology-based approach, that included two independent cohorts, we demonstrate that preeclampsia, and moreover, placental inflammation is protective of ROP development. Data further suggests that protein changes in HTRA1 and TGFb-1 underlie the pathomechanisms between placental inflammation and ROP development.

ABSTRACT BODY:

Purpose: High-temperature requirement protein A1 (HTRA1) is a serine protease secreted by a number of tissues including the retinal pigment epithelium (RPE). The purpose of this study was to characterize the retinal phenotype of an Htra1 gene knock-out ($Htra1^{-/-}$) mouse model to understand the role of HTRA1 in retinal pathology.

Methods: The ocular phenotype of these $Htra1^{-/-}$ mice was studied by evaluation of gross morphology, fundus imaging, and electroretinography (ERG) at ages 5 and 19 months. For further evaluation, retinal morphology and expression of relevant marker genes and proteins were evaluated by immunohistochemistry (IHC) and quantitative real time PCR (qRT-PCR) of 19 months old $Htra1^{-/-}$ mice and compared with age matched controls.

Results: ERG responses in the $Htra1^{-/-}$ mice were highly reduced compared to wildtype mice as early as 5 months and progressed until 19 months. A significant loss of short wavelength cones ($p<0.0001$) and medium wavelength cones ($p<0.0001$) was observed in $Htra1^{-/-}$ mice compared to the age-matched controls by IHC at 19 months. A significant reduction in the level of expression of Opn1sw/S-opsin ($p=0.0002$), Opn1mw/M-opsin ($p=0.0002$) and Rho/Rhodopsin ($p=0.0002$) transcripts was noted at 19 months by qRT-PCR. In addition, the expression of HTRA1 protein was not detected in $Htra1^{-/-}$ mice retina. A significant increase in the expression of other macular degeneration (MD) associated genes, C1qtnf5/Ctrp5 ($p=0.0008$), Timp3 ($p<0.0001$) and Efemp1 ($p=0.0008$) were observed in $Htra1^{-/-}$ mouse by qRT and IHC at 19 months. Whereas expression of the RPE markers ZO1 ($p=0.0023$) and MERTK are significantly lower at 19 months. Progressive accumulation of auto-fluorescent spots close to retinal vessels were observed at 5 months and 19 months of age. Evaluation of retinal phenotype including ultrastructure analysis by electron microscopy (EM) at multiple younger ages is in progress.

Conclusions: The $Htra1^{-/-}$ KO mice showed loss of photoreceptors, decrease in the expression of rod, cone, and RPE markers and abnormal photoreceptor function. In addition, accumulation of extra cellular matrix (ECM) components associated with MD phenotype was also noted suggesting a possible role for HTRA1 in retinal and macular degeneration pathology.

TITLE: Hypoxia adaptation is essential for Aspergillus fumigatus virulence in the cornea

SESSION TITLE: Modulation of ocular surface immunity during health and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.K. Fuller, E. Adams, Ophthalmology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|K.K. Fuller, J.D. Lightfoot, Microbiology & Immunology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure: Kevin Fuller: Commercial Relationship: Code N (No Commercial Relationship) | Emily Adams: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Lightfoot: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: For internal organs, such as the lung, fungal infection drives the development of tissue hypoxia due to inflammation, vascular occlusion and necrosis. It is unknown however whether the cornea –a thin tissue with ostensibly good access to atmospheric oxygen– similarly becomes hypoxic during fungal keratitis (FK). In this study, we tested development of corneal hypoxia, as well as the role of fungal hypoxia adaptation, in the pathogenesis of Aspergillus fumigatus keratitis.

Methods: C57BL/6J mice were immunosuppressed with methylprednisolone on the day preceding inoculation. The next day, corneas were abraded with an algerbrush and topically inoculated with germinated A. fumigatus spores. To measure tissue hypoxia, animals were injected with pimonidazole (Hypoxyprobe) 90 min prior to tissue harvest. Ocular sections were imaged by fluorescence microscopy following staining with anti-hypoxyrprobe or anti-Aspergillus antibodies. The srbA gene of A. fumigatus was deleted via a CRISPR-Cas9 approach. For the virulence studies, animals were inoculated with wild-type (WT) or the ΔsrbA mutant and eyes were imaged daily by slit-lamp and optical coherence tomography (OCT). At 24 and 48 h post-inoculation (p.i.), corneas were isolated for histopathology (PASH stain), fungal burden (CFUs) or flow cytometry.

Results: In corneas infected with A. fumigatus, positive hypoxyprobe staining was observed as early as 12 h p.i. and this signal intensity increased 24 and 48 h p.i. Given these results, we hypothesized that a key regulator of the hypoxic response in A. fumigatus, SrbA, would regulate growth within the infected cornea. We first deleted the srbA gene and, consistent with previous reports, found the mutant was unable to grow in vitro at oxygen levels below 3%. In contrast to corneas infected with WT A. fumigatus, those infected with ΔsrbA failed to develop signs of disease (opacification or ulceration), displayed normal corneal structure by OCT, and did not harbor viable fungus. This corresponded with histopathology and flow cytometry, which revealed a lack of inflammatory cells in ΔsrbA-infected corneas.

Conclusions: Taken together, these results support a model in which fungal antigen rapidly drives the development of corneal hypoxia, thereby rendering SrbA essential for fungal growth and virulence. Consequently, proteins essential for fungal hypoxia adaptation could serve as targets for novel FK therapy.

TITLE: Generation of peripherin-2 knock out in Xenopus laevis using Crispr/Cas9

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.M. Tam, O.L. Moritz, Ophthalmology and Visual Sciences, The University of British Columbia Faculty of Medicine, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure: Beatrice Tam: Commercial Relationship: Code N (No Commercial Relationship) | Orson Moritz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Peripherin-2 is an integral membrane protein expressed in rod and cone photoreceptors and is involved in disk morphogenesis. It is specifically localized to the highly curved rim regions of the outer segment disks. The purpose of this investigation was to knock out peripherin-2 in X. laevis to aid in the study of the role and functions of this protein.

Methods: Crispr/Cas9 methodology was used to knock out Xenopus peripherin-2 (xrds38). Multiple PAM sites in the DNA sequence were identified and synthetic guide RNA's were designed and generated by in vitro transcription. sgRNA's were coinjected with Cas9 mRNA into fertilized single cell X. laevis embryos. Injected embryos were raised at 18C on a 12:12 light cycle. At 2dpf (days post-fertilization), whole embryos were used to generate genomic DNA. The region surrounding the PAM site was amplified by PCR and DNA sequence analysis was performed to assess the efficiency of editing. At 14dpf, tadpoles were sacrificed and their eyes were enucleated for western blot and immunohistochemical analysis.

Results: Xenopus laevis are pseudo-tetraploid and have two functional genes (and therefore four alleles) that encode xrds38. Several sgRNA's to different PAM sites were investigated and a single sgRNA (sg3) was identified that efficiently edits both genes based on sequencing of genomic DNA. Western blots and antibody labeling of frozen sections confirmed that a subset of animals generated no longer expressed xrds38 in their retinas. Lack of xrds38 expression did not cause retinal degeneration.

Conclusions: We were able to successfully knock out xrds38 expression in photoreceptors. The lack of retinal degeneration observed is likely because X. laevis also express a second peripherin-2 (xrds35/36) which is highly similar in sequence. Xrds35/36 is not however thought to be an orthologue of rom1. The ability to knock out xrds38 will allow us to obtain further insights into the role of peripherin-2 in disk morphogenesis and outer segment homeostasis. Future studies will include simultaneously knock out of both xrds38 and xrds35/36.

ABSTRACT BODY:

Purpose: During natural viewing, separation of locally moving objects from self-motion-induced global motion is pivotal for safely navigating the world. In many vertebrates, retinal pathways extract local motion from a visual scene. In contrast, no global motion specific pathways in vertebrate retina have been discovered. In primate retina, neither form of motion selectivity has been identified. Here, we recorded from several ganglion cell types in the primate retina, including some of the lesser studied types. In order to test sensitivity to global and local motion, we first assess how global motion affects signal integration, and then measure each cell type's selectivity for local motion relative to global motion.

Methods: Recordings were performed in an intact, in vitro preparation of the macaque monkey retina. Spike responses or whole-cell synaptic currents in ganglion cells were recorded using borosilicate glass electrodes. Neural responses were measured to stimuli that contained local or global motion. Surround-specific motion stimuli were also used to test the effects of motion in the receptive-field surround on cellular responsiveness.

Results: We found pathways in the primate retina that perform computations required for extracting local motion from a visual scene. Additionally, one pathway performs a global motion computation–a novel computation among vertebrate retinas. Further, the receptive field surround was critical in performing these computations. Surround motion shifted sensitivity of responses across cell types, with ganglion cells showing either facilitation or suppression of responses.

Conclusions:

We show here three primate retinal ganglion cells that are selective for local motion, and one that is selective for global motion. We demonstrate that the way in which the receptive field surround affects the receptive field center is key in encoding local and global motion in the primate retina. These results are the first to show that selective processing of local and global motion in the primate visual system begins in the retina.

ABSTRACT BODY:

Purpose: Trachomatous trichiasis (TT) is the leading infectious cause of blindness, and an estimated 1.8 million currently need surgery to prevent blindness. The disease primarily affects individuals living in rural parts of developing countries, which can make case identification challenging. Surgery is provided primarily through surgical camps, making it necessary to identify cases in advance. Currently, community members receive a brief training on how to identify TT and then are tasks with going door-to-door to identify potential cases. However, their success is limited, with only 15%-30% of potential cases actually having TT, and many cases are not identified. The goal of this project was to develop an image recognition algorithm that can identify TT with at least 90% accuracy. Ultimately, the goal of this project is to provide local communities with the ability to identify TT with a high rate of accuracy, which will increase the efficiency of TT surgery programs.

Methods: We utilized images from an ongoing TT surgery clinical trial in Ethiopia to develop the algorithm. We designed segmentation and patching software to identify the regions of interest (the upper eyelid) and to indicate areas of the eyelid with and without TT. We trained neural networks to classify each eyelid as having TT present or absent. We then created a smartphone app that incorporates the algorithm that can be used by local community members to identify patients with TT. We conducted a field evaluation in Mozambique to determine how well individuals can take high-quality images using the app.

Results: We utilized over 5,000 images of eyes with and without TT to train and test the algorithm. The algorithm currently has a sensitivity of 92% and specificity of 87%. Six individuals were trained on use of the app and they tested the app over a 5-day period in 2 districts in Mozambique. They took 991 images with the app. The majority of the images were of acceptable quality for the algorithm to process. Over 98% of community members were willing to have their eyelids imaged in order to evaluate the algorithm and app.

Conclusions: This study demonstrated strong potential for machine learning to identify eyelids with TT. Future research should evaluate the effectiveness of this approach across multiple trachoma-endemic countries.

TITLE: Pupil recovery dynamics following melanopsin activation with suprathreshold stimuli

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Pothiadia Irungovel, T. Trinh, S. Viswanathan, SUNY College of Optometry, New York, New York, UNITED STATES|A. Hartwick, Optometry, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Ashwin Badrinath Pothiadia Irungovel: Commercial Relationship: Code N (No Commercial Relationship) | Toan Trinh: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Hartwick: Commercial Relationship: Code N (No Commercial Relationship) | Suresh Viswanathan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the dynamics of pupil redilation following melanopsin activation with suprathreshold light stimuli.

Methods: Consensual PLR was recorded from normal subjects (n=4, 23-53 years of age) using a custom pupillometer (Diagnosys LLC) to full-field blue (450nm) LED test stimuli of -3.47 log W/sr/cm^2 (14.88 log photons/cm^2/sec) presented to the dilated fellow eye following 5 minutes of dark adaptation. PLR and its recovery was sampled from 3 seconds prior to stimulus onset till 16 minutes after stimulus onset for several durations of the test stimuli in the range of 5 – 120 seconds. Maximal constriction and Post Illumination Pupillary Response (PIPR) at 6 seconds after stimulus offset and for 10 seconds each minute thereafter was calculated. The responses following light offset was fit with an equation of the form $y = a\,(1\text{-}e^{-bx})$ that describes the exponential increase in pupil diameter to the maximum.

Results: Pupil diameter was reduced to 40% (±5) of the pre-stimulus baseline diameter and was similar for all stimulus durations and was sustained for the entire duration for which the test stimuli were presented. The 6s PIPR was 58% (±6%) of the pre-stimulus baseline diameter and PLR recovered to 85% (±3.5) of pre-stimulus baseline diameter by 16 minutes following light onset for all stimulus durations. The time constant b in the equation describing the exponential rise to maximum gradually increased from 0.37 to 0.9 as stimulus duration increased from 5 to 120 seconds.

Conclusions: Suprathreshold test stimuli for melanopsin activation elicit prolonged tonic constriction of the pupil that can take a significant amount of time to recover back to baseline. These preliminary results highlight the importance of allowing adequate inter-stimulus interval durations while performing repetitive testing of PLR with suprathreshold stimuli for melanopsin activation.

ABSTRACT BODY:

Purpose: Ocular Mucous Membrane Pemphigoid (OcMMP) is a chronic autoimmune condition that causes progressive cicatrizing conjunctivitis and shortening of the fornices. Our goal was to investigate the long-term outcomes of fornix reconstruction and cicatricial entropion repair in patients with OcMMP.

Methods: Patients with a diagnosis of OcMMP that underwent fornix reconstruction (with amniotic membrane/buccal mucosal graft) or cicatricial entropion repair by the same surgeon (PJD) between January 1, 2000, to September 1, 2020, were analysed. Patients included in the study had a positive biopsy suggesting OcMMP and/or clinical features of OcMMP or pseudo-pemphigoid. Patients were graded from stages 1 to 4 according to the Foster Classification. The primary outcome was the overall success of fornix reconstruction based on whether there was restoration of a deep fornix at the last follow up appointment. Secondary outcomes included areas of trichiasis, restriction in ocular motility and visual loss from corneal injury.

Results: Ten patients with a diagnosis of OcMMP (80% Foster classification of 3-4) were enrolled (5 males and 5 females, median age: 78) as well as three patients with pseudo-OcMMP (2 females and 1 male, median age: 88). Mean follow up time was 24.9 ± 29.1 months from the initial surgery. Six of the OcMMP patients underwent fornix reconstruction and five underwent entropion repair. In eight OcMMP patients with consistent follow-up, loss of fornix depth or reformation of symblepharon was found on average at 7.1 ± 7.0 months post-operatively. Only one OcMMP patient maintained a deep fornix and half of the patients required an additional corrective surgery. Three patients had an average decrease in visual acuity of 1.75 ± 1.09 logMAR and went on to have evisceration or enucleation surgeries. Recurrence of trichiasis occurred in all but one patient. Eight patients were on systemic immunosuppressive therapy at the time of surgery, but there was no difference in success of outcome between medically treated and non-treated cases. Pseudo-OcMMP patients were noted to have short-term benefit from surgical intervention.

Conclusions: This is the first study reviewing the long-term outcomes of fornix reconstruction and cicatricial entropion repairs in cases of OcMMP, and while initial results are beneficial, these largely reverse an average of 7 months following the interventions.

SUBMITTER (NAME ONLY): Mary Whitman

TITLE: Investigation of extraocular muscle development in a mouse model of infantile nystagmus syndrome

SESSION TITLE: Nystagmus and Strabismus: Genetics, animal models and imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Whitman, S.K. Vemula, S. Kim, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|M. Whitman, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Mary Whitman: Commercial Relationship: Code N (No Commercial Relationship) | Sampath Vemula: Commercial Relationship: Code N (No Commercial Relationship) | Seoyoung Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infantile nystagmus syndrome (INS) is characterized by involuntary oscillatory eye movements, beginning in infancy. Eye muscle specimens from patients with INS display an increased proportion of slow myosin heavy chain (MyHC) positive muscle fibers and alterations in the neuromuscular junction. It is unknown if these changes are the cause or effect of long-standing nystagmus. Using albino mice as a model of infantile nystagmus, we examined the development of extraocular muscles and their innervating motor neurons during postnatal development.

Methods: We examined the extraocular muscles of postnatal day (P) 0, P10, P14, P21, 6 and 12 week old albino mice and littermate wild-type controls. Balc/c albino mice were crossed to mixed background pigmented mice, and heterozygous mice were crossed to generate experimental litters. Using immunostaining, we compared slow and fast myosin heavy chain (MyHC) composition between control and albino mice extraocular muscles (EOMs) (n=3-6 animals of each genotype at each timepoint). Data were analyzed using unpaired student’s t-test.

Results: In control animals, there is a higher proportion of slow MyHC fibers at P0 (5.28±0.53%), with decreasing expression over time (1.37± 0.12% at 12 weeks), consistent with prior reports. In albino mice, the proportion of slow MyHC fibers is similar to controls at P0 (4.84±1.48%), P10 (4.88±3.14%), and P14 (1.04±0.06%). By P21, there is a higher proportion of slow MyHC fibers in albinos (2.52±0.31%) compared to controls (1.23±0.082%), which persists into adulthood (4.22±1.27% slow MyHC fibers in albinos, 1.37± 0.12% in controls at 12 weeks).

Conclusions: Albino mice, who display nystagmus, have an increase in the proportion of slow MyHC fibers in their extraocular muscles. This is similar to the findings seen in human samples. We see evidence of this difference as early as P21, but not before eye opening (~P12), suggesting that there may be sensory activity-dependent mechanisms that contribute to EOM development.

ABSTRACT BODY:

Purpose: To evaluate the relationship between gender and the prevalence, and severity, of trachomatous scarring (TS) in a formerly trachoma hyperendemic district.

Methods: A cross-sectional study was conducted amongst adults in Kongwa District, Tanzania. Participants underwent ocular examination. The presence and severity of TS was evaluated in photographs of the everted upper eyelid of each eye. The TS severity was graded using the photographic four step severity scale which goes from S0 (none) to S4 (severe). The analysis was done at the person level; for each participant the more severely affected eye was selected. For the analysis TS was dichotomized; S3 and S4 scars (more severe TS) were grouped together and compared to S0, S1, S2 scars (none to mild TS) which were also grouped together. Logistic regression models were used to examine the association between the age, gender, and TS severity.

Results: A total of 3701 participants were included in this study. We report on a subset of these individuals, 2271 participants. The participants' mean age was 35.8 years (range: 15-94, SD 17.2) and 61% were female. Males and females had similar prevalence of minimal (S1) and mild (S2) TS; females had an increased prevalence of more severe TS. Figure 1 shows the prevalence of more severe TS (S3 and S4 scars) by age and gender. Age was associated with more severe TS; for every year increase in age, there was a 6.6% increase in the odds of having more severe TS (95% CI: 5.8%, 7.4%). More severe TS was seen in females; females were 2.61 times more likely to have more severe TS compared to males (95% CI: 1.95, 3.50).

Conclusions: Gender and age are positively associated with more severe trachomatous scarring. The significantly increased odds of more severe trachomatous scarring in females in this study suggests that focusing on reasons why women develop more severe scarring could yield a pathway by which to reduce the risk of developing downstream potentially blinding trachoma sequalae.

ABSTRACT BODY:

Purpose: Changes in ocular power during accommodation are the result of changes in lens shape. Yet, few studies have quantified the relation between ocular biometry and objective accommodative response. These studies typically rely on static measurements repeated at multiple accommodative demands. The goal of this project is to develop an instrument to dynamically measure the relation between changes in refraction and ocular biometry during accommodation.

Methods: The combined system includes a Shack-Hartmann aberrometer to measure refraction, a fixation target to stimulate accommodation, and a previous whole-eye OCT system for biometry (Ruggeri et al, Biomed Opt Exp 2012). The fixation target uses a two-channel Badal system that generates either step and ramp stimuli with vergences ranging from -20 D to +10 D. Refraction and OCT biometry are recorded sequentially by flipping a dichroic mirror. OCT images are processed using a semi-automatic segmentation software to quantify corneal and lens curvatures and intraocular distances. Accuracy of the refraction was assessed by comparing measurements on 23 eyes of 12 subjects (SE range: -9.25 to 2.25 D) with measurements acquired with a commercial autorefractor (KR-800, Topcon). Accommodation responses of three human subjects (ages = 21, 27, 31 years) to three ramp stimuli (2, 4, and 8 D at 0.25 D/s) were recorded in triplicate 25Hz (refraction) and 8.7 Hz (OCT). The responses were analyzed to correlate changes in refraction and biometry.

Results: Bland-Altman analysis shows a mean difference between the clinical autorefractor and custom-made aberrometer of -0.02 D ± 0.9 D (95% confidence limits). The accommodative responses of all three subjects had a similar behavior, with a 6 s latency followed by a linear response with time or accommodative demand up to maximal accommodation.

Conclusions: We demonstrate the feasibility of combined dynamic objective refraction and biometry during accommodation. Dynamic recordings provide faster and more precise quantification of accommodative responses.

ABSTRACT BODY:

Purpose: Presence of fluid on optical coherence tomography (OCT) in age-related macular degeneration (AMD) is considered a biomarker of neovascular activity. However, recent evidence has shown that fluid does not always indicate neovascularization. Our goal was to describe non-neovascular fluid in AMD and its response to anti-VEGF treatment or observation.

Methods: This observational case series included AMD eyes with macular drusen and/or drusenoid pigment epithelial detachment associated with non-neovascular fluid. OCTA was performed in all eyes to exclude the presence of macular neovascularization at multiple visits. Subretinal fluid (SRF) was tracked and measured to determine the response to anti-VEGF therapy and observation without injections.

Results: 10 eyes of 9 patients with intermediate AMD and SRF were studied over a median period of 54 months (Range: 5.5 months-10 years). Median visual acuity at first visit with documented fluid in logMAR was 0.2 (Snellen equivalent 20/30) with a range of 0-0.4 (20/20–20/50). 6 eyes had a history of anti-VEGF therapy with a median number of 3 injections (Range: 3–27 injections). Median follow-up while receiving injections was 3.5 months (Range: 2–48 months) while median follow-up off injections was 12 months (Range: 4-43 months). None of the eyes responded to anti-VEGF injections except for one eye that showed a response after 1 injection but no response after subsequent injections. SRF thickness remained stable and unchanged during the follow-up off injections in all eyes (n=6) with prior injection and in all eyes (n=4) never injected. 5 out of the 10 eyes developed geographic atrophy and CRORA and one eye developed IRORA and all eyes exhibited at least 2 out of 5 OCT biomarkers of atrophy.

Conclusions: This study provides preliminary data regarding the progression of non-neovascular fluid in AMD with or without anti-VEGF injections. A possible mechanism for fluid development may be related to RPE pump impairment. Distinguishing neovascular versus non-neovascular fluid using multimodal imaging, including OCTA, is essential to avoid unnecessary anti-VEGF injection.

Commercial Relationships Disclosure: Rodrigo Abreu: Commercial Relationship: Code N (No Commercial Relationship) | Jose Natan Rodriguez-Martin: Commercial Relationship: Code N (No Commercial Relationship) | Juan Donate-Lopez: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Blair: Commercial Relationship: Code N (No Commercial Relationship) | Sandro De Zanet: Commercial Relationship: Code N (No Commercial Relationship) | Jose Rodrigo: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Bermúdez-Pérez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study was to apply an artificial intelligence (AI) algorithm, through deep learning, for the optimized development of an automated diabetic retinopathy (DR) detection algorithm using retinographies and to study the consistency of retina ophthalmologists with the artificial intelligence system in DR screening under routine clinical practice conditions.

Methods: A clinical practice retinographies dataset were used to train an algorithm formed by two component networks which were independently optimized, with the outputs combined to give a single classification for DR. For evaluation, an international standardized retinography dataset in diabetic retinopathy (Messidor-2) was used, which were evaluated by the AI algorithm and two retinal experts with more than 10 years of experience, from different autonomous regions and health systems and diabetic retinopathy screening programs in a blind and independent manner. No prior unification of diagnostic criteria (DR) was performed among the observers to simulate conditions of routine clinical practice, the grades to be used being: absent DR, mild DR, moderate DR, severe DR and proliferative DR. The comparative analysis was performed by grouping DR grades into two groups: Non-derivable (absent DR and mild DR) and Derivable (mild, moderate, severe and proliferative DR).

Results: An image training datsetset of 109,628 images was used for the training phase. Both the AI algorithm and retinal experts analyzed the 1744 images in the evaluation dataset each. The consistency results pitting observer 1 and 2 independently against the AI algorithm were as follows, respectively: a sensitivity of 0.99 and 1; a specificity of 0.74 and 0.71; and an area under the ROC curve of 0.87 and 0.86.

Conclusions: In the current state, our deep learning-based algorithm for retinography-based screening of diabetic retinopathy develops behavior aligned with that of expert retinal ophthalmologists under routine clinical practice conditions. There is the possibility of applying this algorithm in clinical practice with the aim of improving health outcomes compared to the current standard of ophthalmologic management of diabetic patients.

ABSTRACT BODY:

Purpose: Declining reimbursement and rising costs of labor, operating space, and equipment are threatening the financial health of large academic medical centers. Our goal is to use electronic health record (EHR) time logs and the cost per unit of each resource to calculate the complete cost profile of upper eyelid surgery using time-driven activity based costing (TDABC) analysis. The TDABC analysis uses a bottom up, process based approach to determine resource utilization and estimate cost compared to the level of maximum Medicare reimbursement in the hospital setting.

Methods: Using TDABC analysis, we calculated the cost of healthcare resources consumed for patients undergoing elective upper eyelid surgery (CPT 15822, 15823, 67901, 67903, 67904, 67908) at Vanderbilt University Medical Center (VUMC) in fiscal years 2018-2020. We devised an upper eyelid surgery process flow map and used de-identified time-stamped logs extracted from the EHR, averaged across 154 unique patient encounters, to categorize pre-operative, peri-operative, and post-operative durations. We used cost per minute data for space and equipment, personnel, materials, and overhead provided by the VUMC financial management office for cost allocation. This study was approved by Vanderbilt Institutional Review Board.

Results: TDABC analysis resulted in a total cost of $5393.72 per patient, which is $1706.91 more than the average maximum Medicare reimbursement of $3686.81 for the six upper eyelid procedures studied. Upper eyelid surgery cases do not reach breakeven unless the case duration is less than 39.97 minutes, overhead is reduced by 48.6%, or reimbursement is increased by 46.3%.

Conclusions: The analysis demonstrates that true costs for upper eyelid surgery are significantly greater than the maximum allowable Medicare reimbursement for a hospital setting. Reimbursement is inadequate even under ideal capacity constraints with fully available ORs and full copayment from every patient.

Upper eyelid surgery TDABC analysis can guide surgeons and administrators in providing higher value, lower cost care by optimizing processes, settings of care, and allocating resources judiciously. Ophthalmology departments in academic hospital settings may also benefit from accurately measured upper eyelid surgery costs to inform policy discussion regarding appropriate reimbursement.

TITLE: A comparative study on the efficacy of netarsudil versus brimonidine in eyes already being treated with anti-ocular hypertensive medications

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Pham, C. Bradley, C. Casey, J. Yohannan, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Alex Pham: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Corinne Casey: Commercial Relationship: Code N (No Commercial Relationship) | Jithin Yohannan: Commercial Relationship(s);Code C (Consultant/Contractor):Abbvie, Genetech, Ivantis

ABSTRACT BODY:

Purpose: To evaluate the impact of the addition of netarsudil compared to brimonidine in glaucoma patients requiring more than two baseline glaucoma medications for intraocular pressure management.

Methods: A chart review was performed to compare eyes prescribed with netarsudil (n=176) and eyes prescribed with brimonidine (n=193) as a third to fifth agent in the setting of uncontrolled IOP. Five sequential IOP measurements were obtained to determine the mean change in IOP before and after treatment ($\Delta IOP = \text{mean } IOP_{4,5} - \text{mean } IOP_{1,2,3}$). A multilevel linear mixed-effects model assessed the impact of medication (independent variable) on ΔIOP (dependent variable). Additional independent variables of interest included the number of glaucoma medications at baseline, age, sex, glaucoma type and severity, race, and pre-treatment IOP. Multiple linear regression estimated the effect of both medications as a third to fifth agent. Bootstrap analysis was performed to remove sampling bias and equate the distributions of potentially confounding variables for both netarsudil and brimonidine.

Results: The unadjusted mean ΔIOP for netarsudil and brimonidine was −2.20 and 0.60 mmHg respectively ($p < 0.001$). The linear mixed-effects model showed that netarsudil significantly improves IOP by 2.30 mmHg more than brimonidine. However, bootstrap analysis revealed both medications demonstrated statistically similar benefits. Both the mixed-effects model and bootstrap analysis showed diminishing effects of both medications with an increasing number of other glaucoma medications at baseline, albeit this trend was not significant in the mixed-effects model. Specifically, the multiple linear regression model revealed the estimated ΔIOP of netarsudil and brimonidine when added as a third, fourth, and fifth agent is −3.18, −2.49, and −1.79 mmHg; and 0.13, 0.82, and 1.51 mmHg, respectively. Both medications failed to control IOP at similar rates, leading to additional laser and surgical interventions in subsequent follow-up in approximately a third of eyes.

Conclusions: When escalating pharmacologic therapy, netarsudil and brimonidine are comparable options in terms of efficacy. Both medicines have diminishing effectiveness when added in eyes with more glaucoma medications at baseline. Clinicians should consider individual costs and tolerance when deciding the most appropriate treatment.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) has been defined as a major complication of rhegmatogenous retinal detachments (RRD). We seek to describe the phenomenon of PVR development in patients with horseshoe retinal tears (HST) in the absence of a preceding RRD.

Methods: This is a retrospective case series of patients who initially presented with retinal tears without rhegmatogenous retinal detachment. Patients with history of retina surgery or RRD prior to retinal tear diagnosis were excluded. PVR was defined according to the standard PVR classification. We analyzed the associated risk factors predisposing the patients to PVR development including presence of vitreous hemorrhage, phakic status, patient factors (e.g., myopia, smoking history), and interventional history (laser retinopexy vs. cryotherapy and the number of laser spots).

Results: Eight patients with PVR development following a HST were identified. The median age was 55.5 years old. Five patients were male. Three of 8 patients identified as former smokers. All 8 patients were myopic. Seven of 8 patients are phakic. All 8 patients presented with vitreous hemorrhage at the time of retinal tear diagnosis. Seven patients had 1 HST at the time of diagnosis and one had 2 HSTs. Seven of 8 patients had laser retinopexy and 1 patient had cryo-retinopexy. In the 7 patients with laser retinopexy, 5 of 7 had laser retinopexy with greater than 700 laser spots. Three patients were identified as having Grade B PVR, and 4 patients had Grade C PVR (1 unknown grade). Six out of 8 patients required retinal surgery for PVR retinal detachments. The other 2 patients required surgery for epiretinal membrane.

Conclusions: While proliferative vitreoretinopathy is classically defined as a complication following rhegmatogenous retinal detachment, we describe a series of patients who develop PVR following retinal tear without detachment. Vitreous hemorrhage was a uniting risk factor in this case series. Our case series suggests that PVR can develop within a spectrum from retinal tears to RRD. Awareness of this potential complication of HST may aid in patient education.

ABSTRACT BODY:

Purpose: It is extremely difficult to clinically differentiate between ocular immune-related adverse events (IrAEs) of immune checkpoint inhibitors (ICIs) and paraneoplastic-associated retinopathy. Although rare, early detection of IrAE retinopathies is essential, given the degree of tissue damage is often disproportionate to the symptoms. The purpose of this study is to exaCancmine and discuss the diagnostic challenge of distinguishing between melanoma-associated retinopathy and immune checkpoint inhibitor (ICI) related retinopathy - which poses a unique diagnostic challenge.

Methods: Dilated fundus exam (DFE), electroretinogram (ERG), MRI, PET scan, cytokine panel, and a literature search were conducted.

Results: A 55-year-old male with a history of metastatic malignant melanoma of left forearm Stage IV (rpT2a, pN0, cM1c) on ipilimumab and nivolumab presented with symptoms of nyctalopia, diminished color contrast and light/dark contrast, abnormal visual phenomena, and constricted visual field OU. The exam showed 20/20 vision OU, bilateral color vision deficiency (9/14 OD and 10/14 OS), and no RAPD OU. The DFE showed no optic nerve swelling, pallor, or retina abnormalities. ERG did not show the classic “electronegative response” which we would expect to see with MAR. Instead, we see a normal b-wave and absent a-wave which denotes pure rod dysfunction. Thus, the patient’s symptoms are likely attributed to an ICI-related adverse event such as bilateral retinal vasculitis.

Conclusions: Although severe and insidious in nature, ocular IrAEs are a lesser-known effect of ICIs in the medical community; moreover, even in specialized oncology clinics, it is still extremely difficult to diagnose due to the ambiguity of the disease. Further, immediate appropriate treatment through discontinuation of ICI and starting a trial of steroids, IVIG, and PLEX is necessary for ocular IrAEs to prevent permanent vision loss. Especially, given that these retinopathies often require further specialized testing such as ERGs or mfERG to differentiate between them and cancer-related retinopathies, recognition by oncologists and early referral to an ophthalmologist is essential.

ABSTRACT BODY:

Purpose: To describe the clinical, structural, and functional features of RPE65 mutation related Leber congenital amaurosis (LCA) in a Mexican cohort.

Methods: A descriptive, observational, and transversal study was carried out. Twelve unrelated patients with molecularly and clinically diagnosed RPE65-LCA were included. Visual function studies included best-corrected visual acuity (BCVA), refraction testing, Farnsworth-Munsell D-15 test, full-field electroretinography (ERG), Full Field Stimulus Threshold test (FST), Goldmann kinetic visual field, chromatic perimetry, and microperimetry. In addition, spectral domain optical coherence tomography (SD-OCT) and autofluorescence (AF) imaging (488 nm and 532/633 nm) were performed in all patients. Measures of central tendency were utilized to analyze the data.

Results: Twenty-four eyes of 12 patients (ages 10-32) were analyzed. The BCVA ranged from 20/50 (snellen) to light perception and the average was of 1.09 ± 0.75 (logmar). There were no detectable rod and cone ERGs in all patients. By FST (analyzed in 17 eyes), 82% (n=14) presented a rod- and cone-mediated function while the remaining 18% (n=3) presented only a cone-mediated function. The extent of kinetic fields varied widely regardless of the age and only 25% (n=6) of the eyes detected a III4e stimulus (range of 5-70 degrees of remaining central vision). In the chromatic perimetry, the mean global deficit of rod- and cone-mediated function was of 46.8 ± 9.1 dB and of 31.0 ± 7.1 dB respectively. Absent (n=20) or minimal (n=4) AF was observed in both short and long wavelength AF images. On average, the horizontal extension of the ellipsoid zone (EZ) was of 3366 ± 3047 µm and the subfoveal outer nuclear layer (ONL) thickness was of 53 ± 29 µm. In the microperimetry (evaluated in 8 eyes), the preferred retinal loci were situated mainly in the fovea-parafovea and superior perifovea.

Conclusions: Accurate diagnosis of RPE65-LCA remains the foremost goal since it allows to stage the degree of retinal degeneration, estimate the prognosis, and tailor the treatment addressing the characteristics of each patient. Our study contributes to the understanding of the genotype-phenotype correlations of this disease in the Mexican population and accentuates the importance of undertaking a multimodal evaluation to identify patients who may benefit from gene therapy.

ABSTRACT BODY:

Purpose: Ocular pain (OP) causes significant morbidity and negatively impacts the quality of life for millions in the United States. However, despite an increased recognition of the importance and prevalence of OP, its diagnosis and management remain challenging because of a lack of understanding regarding the mechanisms underlying OP. We sought to establish a blue light exposure animal model that recapitulates the features of human OP.

Methods: Eight-week-old C57BL/6 mice were reared in cycles of 12-hour of blue light (BL) with 420nm wavelength alternating with 12-hour of darkness . Control mice will be maintained in 12 light/12 dark cycle from white light sources. The changes of behavior were assessed by wind, cold, and chemical stimulation. Corneas or trigeminal ganglion were collected, and immunostaining were performed for tunnel staining, β3-tubutin, SP, TRPV4 or TRPV1. Expression of TRPV1, TRPV4, galanin and SP in corneal projecting neurons (CPNs) were assessed using qPCR.

Results: We discovered that BL-exposure induces hypotonic/hypertonic-induced eye-wiping and decrease tear secretion and stability after cycle 1. The cold-stimulated blinking and wind-stimulated eye-closing behaviors required 3 cycles and their intensities further increased between cycle 7 and 9. Whol e mount confocal microscopy revealed that BL exposure reduced the number of branching of stromal nerve fibers and decreased the density of epithelial nerve endings with increased tortuosity and beadlike fibers/endings. Using neuronal retrograde tracer, the CPNs were identified and most CPNs are both TRPV1 and 4 positive. BL exposure increased the TRPV1 (TRPV1^{high}), but not TRPV4 staining intensity, particularly in some TRPV4 positive CPNs. The CPN enriched TG fraction had significantly elevated mRNA expression of TRPV1, but not TRPV4, as well as neuropeptides, substance P (SP), CNTFRα and NGFR. At the protein levels, certain TRPV1^{high} CPNs are also SP positive in the TG and more SP positive nerve endings in the corneas of BL exposed mice.

Conclusions: Taken together, we established a mouse ONP model suitable for studying mechanisms underlying the pathogenesis and chronicity of OP and showed that BL exposure increases TRPV1 and SP expression in the TG and SP secretion, resulting in the sensitization of nociception and ONP.

ABSTRACT BODY:

Purpose: Differentiated HL-60 (dHL-60; neutrophil-like) cells were treated with the major DR risk factors viz. TNF-α (10ng/ml), IL-1β (10ng/ml), high glucose (HG, 30mM), and precursor of advanced glycation end product-methylglyoxal (MGO, 10μM), for 6 hours. dHL-60 activation was assessed by measuring superoxide level (using dihydroethidium dye, DHE; 5mM) and CD11b expression. The actin cytoskeleton was visualized in TRITC-Phalloidin-labeled cells using an epifluorescence microscope. Cytoskeletal parameters such as F-actin intensity and distribution, and morphological features (cell size and shape) were quantified using ImageJ.

Methods: Differentiated HL-60 (dHL-60; neutrophil-like) cells were treated with the major DR risk factors viz. TNF-α (10ng/ml), IL-1β (10ng/ml), high glucose (HG, 30mM), and precursor of advanced glycation end product-methylglyoxal (MGO, 10μM), for 6 hours. dHL-60 activation assessed by measuring superoxide level using dihydroethidium (DHE;5mM) dye and CD11b expression. The actin cytoskeleton was visualized in TRITC-Phalloidin-labeled cells using an epifluorescence microscope. Cytoskeletal parameters such as F-actin intensity and distribution, and morphological features (cell size and shape) were quantified using ImageJ.

Results: Our findings revealed that, among the aforementioned risk factors and when compared with untreated dHL-60 cells, TNF-α elicits the highest increase in superoxide generation (1.58-fold; $P<0.001$) and CD11b expression (1.26-fold; $P< 0.001$). Further, neutrophil activation by TNF-α correlated with the highest increase (1.12-fold; $p<0.01$) in both cell size and F-actin polarization. In contrast, and rather unexpectedly, HG and MGO treatments caused a reduction in superoxide production, which was consistent with a concomitant reduction in cell size (12%; $P<0.01$) and F-actin polarization (30%; $P<0.001$).

Conclusions: By correlating F-actin changes with superoxide generation, these findings raise the possibility of a potentially novel link between cytoskeletal dynamics and neutrophil activation in early DR. Ongoing studies are aimed at further elucidating the molecular mechanisms by which DR risk factors alter cytoskeletal dynamics in neutrophils and determining whether cytoskeletal modulation in neutrophils is necessary and sufficient to regulate its adhesion to and cytotoxicity toward retinal ECs.

ABSTRACT BODY:

Purpose: The tablet-based Melbourne Rapid Fields (MRF) visual field (VF) test (M&S Technologies, Niles, IL, USA) and IMOvifa virtual reality (VR) VF test (CREWT Medical Systems, Inc., Tokyo, Japan) are portable VF tests that may allow for at-home monitoring and more frequent testing. We compared MRF and IMOvifa outputs to the Humphrey Field Analyzer (HFA) 24-2 Swedish Interactive Threshold Algorithm Standard program.

Methods: In a pilot observational study, subjects who were glaucoma suspects or had a prior glaucoma diagnosis took IMOvifa and MRF tests. All subjects were reliable, experienced HFA testers. We built density plots of average mean deviation (MD) and pattern standard deviation (PSD) and compared MD and PSD group means of each novel device to the HFA. We used paired t-tests to compare sensitivities of 54 corresponding locations from HFA 24-2 also tested on the new devices.

Results: For 50 subjects with an average age of 61 years (range 30-79), MD and PSD for all three devices were not significantly different (MD: HFA vs. IMOvifa CI=[-0.30 to 1.38], p=0.205; HFA vs. MRF CI=[-0.75 to 0.93], p=0.837; PSD: HFA vs. IMOvifa CI=[-0.05 to 1.18, p=0.070]; HFA vs. MRF CI=[-0.65 to 0.57], p=0.905). MRF sensitivities differed from those of HFA at 28 locations, while 23 locations differed for IMOvifa versus HFA. MRF reported greater point sensitivity in the nasal field versus HFA but lower sensitivity in the temporal field. IMOvifa generally reported lower sensitivity versus HFA.

Conclusions: While average MD similarities between the novel devices and the HFA suggest they provide similar results, point-by-point comparisons indicate significant differences. Peripheral point sensitivity differences between MRF and HFA may be related to MRF's flat tablet format versus HFA's spherical bowl format. The IMOvifa had a small bias throughout the field. The small sample size and calculation of MD as a weighted average toward the VF center may explain the lack of difference in MD despite many mostly peripheral differences in sensitivity between each novel device and the HFA.

ABSTRACT BODY:

Purpose: To determine the repeatability of the head-mounted VisuALL Field Analyzer (vFA; Olleyes Inc., Summit NJ) and visual field parameter output correlation with the Humphrey Field Analyzer (HFA; Carl Zeiss Meditec, Dublin CA).

Methods: 45 experienced visual field test takers with an established glaucoma diagnosis and an HFA visual field (HVF) < 3 months were enrolled at a single institution. Both eyes (N=90) underwent portable vFA testing (virtual reality visual field with calibrated light stimuli meant to mimic HFA) on two separate visits. At the first visit, patients completed two vFA tests and one HVF SITA Standard 24-2 for each eye. The order may have started with HVF first if the patient had already completed it as part of their clinical visit during enrollment. Patients who had not already completed an HVF, started with the vFA first before performing an HVF. The second visit occurred within two months of the first visit, in which the patient completed one additional vFA for both eyes.

Results: The mean age of the cohort was 68 years (range of 31-88). Gender distribution was 25,20 (56% male, 44% female). The two baseline vFA tests showed high intravisit test-retest reliability with Pearson correlation coefficient r=0.94 for mean deviation (MD), and r=0.93 for pattern standard deviation (PSD) values. The average MD and PSD values of the two baseline vFA tests also had high Pearson correlation values of r=0.92 and r=0.87 for MD and PSD, respectively. Lastly, the vFA values also demonstrated high intervisit repeatability when comparing the average of the two baseline MD and PSD with the follow up visit (Pearson r=0.9 for MD, and r=0.87 for PSD).

Conclusions: The vFA has a high intravisit and intervisit test-retest reliability at baseline and follow-up among glaucoma patients experienced with perimetry and correlates well with gold standard HFA. The vFA may be a useful clinical tool to enable remote glaucoma monitoring and potentially allow more frequent visual field testing to assess change over time.

ABSTRACT BODY:

Purpose: Studies in several fields of medicine have found that women published less during the COVID-19 pandemic, potentially due to an increase in domestic responsibilities. This study examines whether a similar pattern exists for female authorship in ophthalmology.

In this study, we compared the proportions of female authorship published in high-impact ophthalmology journals before and during the COVID-19 pandemic.

Methods: A cross-sectional study analyzing authorship gender of articles published during the COVID-19 pandemic (between July and September 2020) compared to matched articles published in the same journals before the COVID-19 pandemic (between July and September 2019). Gender of first and last author was analyzed using an online gender determination tool.

Results: A total of 577 articles and 1113 authors were analyzed. There was no significant difference in the average number of publications per male and female author when comparing pre-pandemic to during the COVID-19 pandemic. There was a significant increase in the percentage of female first authorship from pre-pandemic (32%) to during the COVID-19 pandemic (40%, $p=0.01$), but no significant increase in last authorship ($p>0.05$). When analyzing only research articles, a similar increase in female first authorship was noted when comparing pre-pandemic (31%) to during the COVID-19 pandemic (43%, $p=0.02$). No significant differences were noted when analyzing editorials ($p>0.05$).

Conclusions: While disparities continue to exist between male and female authorship, an increase in female first authorship was noted during the COVID-19 pandemic for overall articles as well as research articles.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) continues to present a major challenge to the vision field. With over 11 million patients in the US and 190 million worldwide, AMD is the third leading cause of vision loss in the world. Despite more than 150 years of research at-least 50% of the heritability of AMD remains unclear. Our goal is to take advantage of familial clustering of AMD to gain a better understanding of the genetic factors contributing to AMD development.

Methods: Patients with familial history of AMD seen at the Casey Eye Institute were recruited for the study. Medical and ophthalmologic data and blood samples were collected. DNA was isolated from blood samples, and whole exome/genome sequencing was performed on 554 AMD patients and controls from 127 families. FASTQ files were aligned against human reference genome GRCh38 using BWA (Version 0.7.17). Variants were called by GATK (Version 3.8-1), and annotated with ANNOVAR. Variant and segregation filters were applied to retain only rare and potentially pathogenic variants segregating within at least one family.

Results: Combining classic genetic approaches and bioinformatic tools, we were able to verify associations in 11 previously reported genes, including well established genes such as complement factors, but also newly identified genes such as DCHS2 and DNAH14. This corresponds to only 13% of our families suggesting that there are other contributing genetic factors within our cohort. Notably, 4 genes were found to segregate in more than one family, while the remaining were each found only in one family, underlining the challenges in identification of rare genetic factors. We then performed systematic analysis of WES data to identify segregating rare variants in genes not previously associated with AMD. This analysis yielded 5869 genes. Next, we filtered the list to genes which segregated in 3 or more families, resulting in 330 genes. To identify high confidence candidates, we investigated if they overlaped known AMD loci or belonged to a distinct pathway. This highlighted 2 pathways previously not associated with AMD, lipid transport and sphingolipids. Additional experiments to validate these findings are underway.

Conclusions: We performed genetic analysis on a large familial AMD cohort. Our results corroborate other familial studies and provide new insights in to the molecular pathways contributing to AMD.

TITLE: Comparing microglia and monocyte-derived macrophages in the retina after photoreceptor degeneration

SESSION TITLE: Immunobiology: Ocular Surface, Glaucoma and Retinal Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Ronning, M.E. Burns, Center for Neuroscience, University of California Davis, Davis, California, UNITED STATES|S.J. Karlen, M.E. Burns, Cell Biology and Human Anatomy, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure: Kaitryn Ronning: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Karlen: Commercial Relationship: Code N (No Commercial Relationship) | Marie Burns: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During photoreceptor degeneration monocytes from the periphery can infiltrate the retina and join the resident microglia in the immune response to neuronal loss. After photoreceptor loss is complete ramified macrophages re-tile the retina, but this population remains heterogeneous. Here we compared subtypes of macrophages before and after photoreceptor degeneration.

Methods: Using a light-inducible model of photoreceptor degeneration ($Arr1^{-/-}$ mice), we investigated retinal macrophages before and after photoreceptor degeneration (0 and 20 days of light exposure, respectively). To compare subtypes of macrophages in the retina, we used flow cytometry to quantify cell numbers, immunohistochemistry to quantitatively examine cellular morphologies, and single-cell mRNA sequencing (scRNAseq) to investigate gene expression. All mice were handled according to ARVO, NIH, and UC Davis IACUC guidelines.

Results: After photoreceptor degeneration is complete, the retina contains a heterogeneous population of macrophages. ScRNAseq revealed transcriptionally distinct subpopulations, including one population that highly expressed genes associated with a monocytic lineage in addition to genes similarly expressed by mildly activated microglia, such as Aif1, Lyz2, and Sepp1. Using a fluorescent lineage tracing paradigm to conclusively identify microglia and monocyte-derived macrophages ($Arr1^{-/-}$ $Ai9^{KI/KI}$ $Cx3cr1^{+/YFP\text{-}CreER}$), we find that monocyte-derived macrophages comprise approximately half of all retinal macrophages after photoreceptor degeneration is complete. Additionally, these monocyte-derived macrophages reside alongside bone fide microglia throughout the retina, although they are typically less morphologically complex than the resident microglia.

Conclusions: Following photoreceptor degeneration, a heterogeneous population of macrophages remain in the retina. This population consists of both microglia and monocyte-derived macrophages. The monocyte-derived macrophages adopt a range of microglia-like characteristics, including expression of genes such as Aif1, spatial tiling throughout the retina, and a ramified morphology. However, differences in transcriptional signatures, morphological complexity, and response to further injury suggest these cells with disparate etiologies may remain functionally distinct populations over prolonged periods of time.

TITLE: CALM: A retrospective registry to characterize clinical outcome data for chronic non-infectious posterior segment uveitis patients treated with a 0.18 mg fluocinolone acetonide intravitreal insert

SESSION TITLE: Clinical Uveitis and Scleritis: Therapies and Outcomes

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Seth, R.P. Singh, S. Sharma, Cole Eye Institute, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Kanika Seth: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Code I (Personal Financial Interest):Novartis, Genentech, Regeneron, Alcon, Bausch and Lomb, 41 Gyroscope;Code F (Financial Support):Apellis, Aerie, Graybug | Sumit Sharma: Commercial Relationship(s);Code C (Consultant/Contractor):AbbVie, Alimera, Bausch & Lomb, EyePoint, Regeneron, Genentech/Roche, Clearside;Code F (Financial Support):Gilead, Genentech/Roche, Santen, IONIS

ABSTRACT BODY:

Purpose: Uveitis describes a heterogeneous group of diseases characterized by intraocular inflammation due to either infectious or non-infectious causes. Non-infectious uveitis (NIU) often requires sustained, long-duration therapy, either systemic or local. The fluocinolone acetonide intravitreal (FAi) insert (0.18) is used to treat chronic, non-infectious posterior uveitis by delivering a low-dose, sustained release of FA for up to 36 months. The purpose of this study is to describe the outcomes of the FAi in treating NIU in a real-world database.

Methods: A phase IV, web-based registry system was developed to capture patients treated with the FAi insert from multiple clinical sites, to assess the impact on ocular inflammation using OCT imaging, fluorescein angiography, and visual acuity endpoints. Visual acuity was converted from Snellen equivalent to ETDRS. Safety details, including intraocular pressure and glaucoma interventions, were collected and summarized.

Results: Eight sites have contributed data for 149 eyes of 115 patients with a mean (± standard deviation [SD]) age of 63.7 ± 12.6 (range 19 to 90) to the registry. 60% of the patients are female and 70% are white. The majority of eyes (79.2%) were treated for either posterior or panuveitis. Mean OCT thickness at the time of study entry was 374.1 ± 159.4 microns and average VA was 57.9 ± 25.0 letters. OCT central subfield thickness measurements indicate that 42% of the eyes had a dry central retina at the time of implant. That number increased to 55% at 6 months. 55% of eyes had 20/50 or better visual acuity at baseline and that number increased to 60% at 6 months. Mean baseline IOP was 13.8 ± 4.6 mmHg (range 5 to 30) and increased 1.0 ± 4.9 mm Hg on average at 6 months. The retrospective database will remain open for up to 5 years.

Conclusions: Preliminary data in the CALM registry database indicate effective control of non-infectious uveitis, with improved visual acuity outcomes and without major safety signals. Additional data will be needed to validate these short-term results.

ABSTRACT BODY:

Purpose: To systematically investigate ocular changes in autopsied eyes from fatal cases of Coronavirus disease 2019 (COVID-19) and to investigate the localization of severe acute respiratory syndrome coronavirus (SARS-CoV-2) within ocular structures.

Methods: Macroscopic and microscopic histopathological evaluation was performed and the localization of SARS-CoV-2 RNA within ocular tissues investigated using an in situ hybridization (ISH) technique in 13 eyes. Contralateral eyes were freshly dissected, and droplet digital polymerase chain reaction (ddPCR) assay was performed on ocular fluids and tissues to quantify SARS-CoV-2 RNA.

Results: A total of 21 fatal COVID-19 cases were included (mean age, 60.2 years [range, 27-91 years]; 23.8% female). Histopathological abnormalities include vascular changes (61.9%), cytoid bodies (52.4%), and retinal edema (23.8%) with minimal inflammation (0.09%) were observed. Non-CMV viral inclusions were identified in one eye. No CMV positivity was detected. Of the 21 contralateral eyes tested by ddPCR, 14 tested positive for SARS-CoV-2. Using ddPCR and ISH, SARS-CoV-2 localization was observed in the following ocular tissues and fluid: cornea (27.3%), aqueous (26.3%), lens (54.5%), vitreous (15.0%), retina (22.2%), choroid/sclera (47.4%), and optic nerve (50.0%). The choroid/sclera, optic nerve and lens were the most frequent ocular structures found to be ddPCR positive. Evidence of replication was detected in four cases.

Conclusions: Our results suggest that SARS-CoV-2 localizes to intraocular tissues. However, histological changes observed are likely a secondary hemodynamic change rather than primary effect of the virus.

ABSTRACT BODY:

Purpose: To characterize the ocular phenotype of a novel transgenic mouse strain with a constitutional ocular expression of the IKZF1 isoform, found in humans to be associated with Steven's-Johnson's syndrome (SJS), after immune challenge using the allergic eye disease (AED) model.

Methods: IKZF1 transgenic mice (IK-Tg) were provided by Ueta et al. Experiments were carried out on wild-type (WT) Balb/c and IK-Tg mice aged 8-10 weeks. Both strains underwent immunization followed by a sequential topical challenge using an established model of AED. Clinical eye disease was assessed using (1) an established composite score (2) Meibomian gland plugging, and (3) fluorescein corneal photographs. The challenge-response of each group was compared by calculating the endpoint to baseline change in each score (Δ). Mann-Whitney test was used with a $p<0.05$ cutoff. Molecularly, flow cytometry was used to quantify conjunctival immune cell and submandibular lymph nodes (SMLN) cytokine expression. Fold-increase from unchallenged counterparts was calculated and results of the challenged groups were analyzed descriptively.

Results: After AED challenge, IK-Tg eyes had a significantly larger increase in composite ocular score (Δ ocular score: 5.6 [5.1,6.25] vs 4.8 [4.3,5.25], p=0.001) and Meibomian gland plugging (Δ plugs: 7 [4.25,9] vs 5 [4,6], p=0.01) plus a trend towards higher increase in corneal staining (Δ fluorescein staining: 3.5 [2.25,5] vs 1 [1,3], p=0.06) compared to challenged WT eyes [n=22/group] (Figure 1). In addition, challenged IK-Tg mice had a higher increase in % eosinophilic composition (5.1 vs 4.3-fold increase) and a higher overall % composition of neutrophils (11% vs 2%) in the conjunctival CD45 population compared to challenged WT mice [n=10/group]. Compared to their unchallenged counterparts, both groups experienced increased CD4 cytokine expression in the SMLNs with IK-Tg having a larger increase in IFN-gamma (1.5 vs 1.1 folds), a lower increase in IL-13 (1.9 vs 2.3 folds), and a similar increase in IL-17 (2.8 vs 2.9 folds) % expression change [n=10/group].

Conclusions: IK-Tg mice are characterized by a unique disease phenotype responding distinctly to immune challenge resulting in added exaggeration of ocular disease which can model the hypersensitivity of ocular inflammatory disorders, more specifically, SJS.

TITLE: Discovering Risk Factors Associated with Open Angle Glaucoma Using a Robust Electronic Health Record (EHR) Database

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Noubani, K.P. Shanmugam, Texas A&M University Health Sciences Center, Bryan, Texas, UNITED STATES|C. Murugesan, M. Raju, Informatics, University of Missouri, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Lema Noubani: Commercial Relationship: Code N (No Commercial Relationship) | Krishna Shanmugam: Commercial Relationship: Code N (No Commercial Relationship) | Charunetha Murugesan: Commercial Relationship: Code N (No Commercial Relationship) | Murugesan Raju: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has been well reported that primary open-angle glaucoma (OAG) is a second leading cause of irreversible blindness across the globe. Identifications of potential risk factors associated with OAG could provide preventive measures to control OAG earlier in the disease progression. In this study, we used a large electronic health record (EHR) database representing a wide demographic to assess risk factors for OAG.

Methods: The OAG study cohort was identified using International Classification of Diseases (ICD) codes. We retrieved a total of 132,504 OAG records from 2001 to 2015 for retrospective analysis using exclusion and inclusion criteria for the study. We assessed the relationship between OAG and selected variables using multivariable logistic regression. Adjusted risk ratios were calculated from fitted logistic models and a p-value of < 0.05 was considered statically significant.

Results: Estimated from the dataset, the overall prevalence of OAG was about 15.3%. The incidence of OAG was higher in African Americans (27.5%) and Asians (13.9%) and a lower incidence was observed among the Hispanic (11.0%) race. When comparing gender, females showed a higher prevalence of glaucoma (16.3%) compared to the male population (15.7%). Furthermore, an adjusted odds ratio analysis from the regression model revealed several potential risk factors including atherosclerosis (1.19; 95% CI 1.13. – 1.51), hypertension (1.32; 95% CI 1.20-1.42) and obesity (1.26; 95% CI 1.1 - 1.40) when compared to the non-glaucoma group.

Conclusions: The results preliminarily suggest that obesity and hypertension may be risk factors for OAG and lead one to believe these disease processes should be explored in further detail. Furthermore, the African American race has a higher risk of developing glaucoma compared to the Caucasian (p <0.05) race. With the use of a massive cohort gathered through the EMR database, the identified risk factors can increase our current understanding of glaucoma risk and can therefore, aid in timely intervention and disease management.

ABSTRACT BODY:

Purpose: Recent data have shown that disruption of nutrient delivery and utilization by photoreceptor cells is a common pathway in regulating cell death in retinal degenerative diseases. Experimental retinal detachment (RD) in rodents is a model of acute outer retinal nutrient stress that leads to photoreceptor apoptosis. The purpose of this study was to optimize flow cytometry markers of outer retinal stress and apoptosis in a rodent model of nutrient stress.

Methods: Methods Experimental RD was created in mice and rats via subretinal injection of 1% hyaluronic acid. 3 days post-RD, retinas were harvested and dissociated into single cells using trypsin. Dissociated cells were either incubated with Annexin-V, propidium iodide (PI), and Phiphi lux (active caspase-8) or fixed and stained with TUNEL and cleaved caspase-8. Z-VAD, a pan-caspase inhibitor, was injected sub-retinally at the time of RD and these markers were assessed 3 days later. Tert-butyl hydroperoxide (TBH) was injected intravitreally (IVT), retinas harvested and dissociated 6 and 24 hours later, and cells incubated with DCFDA, C11-Bodipy, and Calcein-AM to examine oxidative stress using flow cytometry. Cells were gated, and data were analyzed by comparing signals to either isotype controls or unstained cells using FCS Express software (De Novo Software, Ontario, CA).

Results: Statistically significant increases in TUNEL (>17-fold; $p<0.001$) and active Caspase-8 (>17-fold) were observed in RD. Treatment with Z-VAD significantly reduced these markers. To confirm these results, we repeated RD in a previously reported model of photoreceptor neuroprotection, the PKM2 conditional knockout mouse. We confirmed that compared to detached retinas in WT animals, PKM2 cKO mice showed reduced TUNEL staining (>7-fold vs >1.3-fold). In WT mice, TBH-mediated oxidative stress increased DCFDA staining (>2.3 fold) and lipid peroxidation markers (>6.7-fold) as well as reduced viability (>1.7-fold).

Conclusions: Flow cytometry is a sensitive, quantifiable, and reproducible method for measuring apoptosis and oxidative stress in a model of outer retinal nutrient stress. It has the advantage of increased efficiency compared to traditional histologic methods. These flow cytometric methods will be key to assessing novel photoreceptor neuroprotective therapies in a multitude of retinal degeneration models.

ABSTRACT BODY:

Purpose: Conventional elastography usually targets and assesses the biomechanical properties of specific ocular structures, for example, the cornea. However, there are some diseases that are broadly impacted by different structures across the entire eye. Glaucomatous optic neuropathy, for example, is associated with increased stiffness in the cornea, sclera, and iris. Therefore, there is a need to develop a tool that can concurrently quantify the biomechanical properties of multiple ocular structures. In this study, we aim to develop a high frequency array based ultrasonic elastography (HFUE) to meet this requirement.

Methods: A 18 MHz linear array was used for imaging and elastic wave acquisition. The rabbit was first anesthetized and positioned, and a shaker tip was brought into contact with the corneal limbus to initiate the elastic wave. An infusion line and intraocular pressure (IOP) sensor were inserted into the posterior segment of the eye through trocars. The height of infusion line was modulated to elevate the IOP. To capture the elastic wave propagation with fine image quality, the acquisition speed was set to 10 KHz. Pulse-width of shaker was set to 1 ms to induce vibrations while maintaining a broad bandwidth of the elastic wave. Raw data was saved for further analysis. Group velocity was calculated to reconstruct the Young's modulus.

Results: Figure 1 shows the elastic wave mapping of the eye and the corresponding B-mode imaging during different levels of IOP. Figure 2 shows the biomechanical response of cornea, lens, iris, parapapillary sclera (PPS), and optic nerve head (ONH) to the different IOPs levels. The Young's modulus of cornea and iris has a linear relation with IOP, PPS and ONH has an second polynomial relation with IOP, while lens is not affected by IOP.

Conclusions: Our elastopgrahy system can concurrently assess the biomechanical properties of multiple ocular structures and detecting the changes in biomechanical properties associated with changes in IOP.

ABSTRACT BODY:

Purpose: To compare the efficacy of gene therapy using mito-targeted and allotopic expression strategies to treat LHON in mice.

Methods: Adult DBA/1J mice (N=30) were randomly split into three groups and were injected with mitochondria-targeted AAV carrying mutant human ND4 gene (hND4G11778A) to induce LHON. We rescued them at a two-day interval using 1) mito-targeted strategy with MTSAAVs carrying- a) mCherry(n=10), b) wtND4(n=10), naïve (mCherry-mCherry) (n=10) and 2) allotopic strategy (n=20) with MTSAAV carrying a) mCherry (n=10), b) wtND4 (n=10) into both eyes. The rescue of the optic nerve and retina atrophy was evaluated using PERG and TEM.

Results: Our main hypothesis is that the mito-targeted strategy will likely result in a higher delivery efficacy than the allotopic approach making it a quicker and an efficient treatment option for LHON. PERG was performed and mice treated with mito-targeted wildtype hND4 showed a PERG amplitude increase by 34% (p=0.150), 46% (p=0.035), and 83% (p=0.093) respectively at 3, 6, and 12 months after injection, whereas mice treated with allotopic expressed wildtype hND4 increased PERG amplitude by 12% (p=0.594), 21% (p=0.357), 43% (p= 0.012), and 33% (p=0.087).The time course of age-related PERG changes was different between the 2 groups (Interaction age x treatment, P=0.003) (Fig.1A), indicating the efficiency of mito-targeted rescue over allotopic where no significant effect of age (P=0.55) but an overall effect of group on PERG amplitude between the rescued and unrescued mice(P=0.043) was observed (Fig.1B). The significance in amplitude difference (control vs rescue) for mice in mito-targeted strategy (OD, P=0.006; OS, P=0.023) indicates that the rescue efficacy with mito-targeted ND4 compared to allotopic.
TEM revealed that MTND4-rescued mice displayed a shift towards small axons showing that the mito-targeted hND4 efficiently prevented the demise of small axons that are lost in human LHON.

Conclusions: Our data showed that the severe visual loss induced by a mitochondrial disease may be reversed using both mito-targeted and allotopic expressed gene therapy,but mito-targeted therapy likely mediates a quicker and more efficient rescue than the allotopic strategy making it a promising option to treat LHON.

ABSTRACT BODY:

Purpose: Methylenetetrahydrofolate reductase (MTHFR) is a critical enzyme in the folate/methionine/homocysteine pathway. Variants in MTHFR, notably 677C>T, have been associated with glaucoma as well as Alzheimer's disease and vascular dementia, suggesting an overlapping mechanism in brain and eye. However, mechanisms driving increased risk are not known, hindering the development of new treatments. Approximately 30% of individuals carry at least one copy of MTHFR$^{677C>T}$, causing a 50% decrease in MTHFR enzyme efficiency. Reduced efficiency can lead to high levels of homocysteine in blood, resulting in vascular inflammation and increased risk for vascular damage. We hypothesize that vascular-specific expression of MTHFR$^{677C>T}$ drives damaging effects in the retinal vasculature, priming the environment for additional risk.

Methods: CRISPR technology was employed to engineer the Mthfr$^{677C>T}$ allele into C57BL/6J (B6) mice. Characterization of the Mthfr$^{677C>T}$ retina includes: RNAscope to determine MTHFR expression, assays to examine MTHFR enzyme activity and relevant metabolite levels, retinal wholemount immunostaining to evaluate vascular abnormalities and inflammatory markers, retinal cross-section immunostaining to examine neuronal layer thickness and glial reactivity, and in vivo OCT and Micron IV imaging as well as pERG to assess retinal morphology and ganglion cell function, respectively.

Results: Previous data show Mthfr$^{677C>T}$ mice phenocopy the human condition — mice show a 50% reduction in MTHFR enzyme activity in liver and brain, elevated levels of plasma homocysteine, altered brain metabolites associated with the methionine cycle, as well as morphological and functional changes in cerebrovasculature. We anticipate similar phenotypes will arise in retinas of our young (6 month) and aged (18 month) cohorts of Mthfr$^{677C>T}$ mice, and are focusing on examining blood retinal barrier integrity using leakage assays and assessing endothelium, vascular smooth muscle, pericytes, basement membrane and tight junctions by immunostaining. Current data support our hypothesis with Mthfr$^{677C>T}$ mice showing evidence of retinal arterial tortuosity.

Conclusions: We have created a novel mouse strain to determine the precise mechanisms by which MTHFR$^{677C>T}$ increases risk for vascular dysfunction with age and in neurodegenerative retinal disease.

ABSTRACT BODY:

Purpose: Pseudomonas aeruginosa is the most common cause of contact lens-related bacterial keratitis; overnight wear is the most important risk factor irrespective of lens type. Silicone hydrogel lenses with high oxygen permeability are FDA-approved for continuous overnight wear, typically for 1 week to 1 month. In this study, we compared outcomes of Pseudomonas aeruginosa keratitis (PAK) between patients wearing extended-wear (EW) versus standard soft contact lenses.

Methods: This retrospective cohort study includes 145 sequential cases of PAK in soft contact lens wearers (SCLW) at a single academic site from 1/2006 to 9/2019; 127 cases occurred in standard SCLW and 18 cases in EW SCLW. P values were calculated using unpaired 2-tailed Student's t-test for continuous variables or chi-squared or Fisher's exact test for binary variables.

Results: Mean age was 36.4 ± 18.1 years in standard SCLW and 56.8 ± 18.9 in EW SCLW ($P<0.0001$), and average time to presentation was 2.66 ± 2.55 days in standard SCLW and 4.22 ± 4.62 days in EW SCLW ($P=0.033$). Overnight wear of contact lenses was reported by 71 (55.9%) of standard SCLW and 17 (94.4%) of EW SCLW ($P=0.0014$). Corneal stromal thinning was present in 59 (46.5%) of standard SCLW and 10 (55.6%) of EW SCLW ($P=0.47$). Maximal stromal thinning was 18.4 ± 29.4% in standard SCLW and 29.4 ± 36.1% in EW SCLW ($P=0.15$), and a procedure (corneal glue, amniotic membrane, or penetrating keratoplasty) was required for progressive stromal thinning in 16 (12.6%) of standard SCLW and 3 (16.7%) of EW SCLW ($P=0.71$). The length of antibiotic treatment was 50.6 ± 67.2 days in standard SCLW and 78.3 ± 97.2 in EW SCLW ($P=0.15$). Final logMAR visual acuity was 0.75 ± 0.83 in standard SCLW and 0.83 ± 0.85 in EW SCLW ($P=0.71$).

Conclusions: Outcomes of PAK were similar between EW and standard SCLW. While not significantly different, a trend existed toward an increased rate of progressive stromal thinning and a longer course of antibiotic treatment in patients wearing EW contact lenses. Final visual acuity and need for a procedure for corneal stromal melting was similar between the two groups.

TITLE: Visuo-motor assessments of eye-brain diseases using infrared oculography

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Yu, M. Shariati, Y.J. Liao, Stanford University School of Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Miaomiao Yu: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Ali Shariati: Commercial Relationship: Code N (No Commercial Relationship) | Yaping Liao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infrared oculography is a noninvasive method of assessing visuo-motor behavior by acquiring time series data. While this technique is widely deployed in eye clinics for improving reliability of visual field attestation and ophthalmic imaging, it is not widely used for diagnostic purposes. The current study aims to curate and analyze a detailed oculography dataset from neuro-ophthalmic patients using novel rapid number reading paradigms. Our goal is to highlight the oculography features associated with each number reading test that best distinguish patient groups with visuo-motor dysfunctions, namely vision loss, eye movement disorder, and Parkinson's disease.

Methods: We performed 1059 recordings using 500-Hz 2-dimensional infrared oculography (RED500, SensoMotoric Instruments (SMI), Germany) in 111 participants (healthy controls and patients with clinically diagnosed eye-brain diseases) who have had careful clinical neuro-ophthalmic assessments. We used regularly and irregularly spaced variations of the King-Devick (KD) rapid number reading test (each one 40 numbers per page, 3 pages total) and extracted time series oculography data using commercial software BeGaze (SMI) and Python scripts. Fixation, saccade and blink parameters were analyzed using biostatistical methods.

Results: Initial power analyses conducted showed regularly spaced number reading paradigms to be good assessments of visuo-motor dysfunction. One-way ANOVAs revealed that significant effects of patient group in 4 out of 13 oculography features. Fixation count, saccade count, total saccade duration and total reading time, were significant for all three KD test variations. Effect sizes were also greater for eye movement disorders (nystagmus and cerebellar ataxia), and Parkinson's disease (most common neurodegenerative disease with ocular-motor manifestations) as compared to those with vision loss (homonymous hemianopia, severe optic neuropathies), highlighting the efficacy of such reading paradigms in diagnosing neuro-ophthalmic diseases associated with visuo-motor dysfunction.

Conclusions: The results indicate fixation count, saccade count, saccade duration and total reading time as reliable features for distinguishing the visuo-motor abnormality in patients with vision loss, ocular motor dysfunction, and Parkinson's disease. Within reading paradigms, regularly spaced paradigms are better indicators of patient group than irregularly spaced.

Commercial Relationships Disclosure: Elena Solli: Commercial Relationship: Code N (No Commercial Relationship) | Wang Jui-Kai: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Branco: Commercial Relationship: Code N (No Commercial Relationship) | Tobias Elze: Commercial Relationship: Code N (No Commercial Relationship) | Randy Kardon: Commercial Relationship: Code N (No Commercial Relationship) | Louis Pasquale: Commercial Relationship: Code N (No Commercial Relationship) | Mark Kupersmith: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Convolutional neural networks (CNNs) trained on large datasets of fundus photographs differentiate normal from eyes with papilledema but quantifying and grading the papilledema has been limited. Our study investigated if: (1) CNN models can quantify optical coherence tomography measurements for each photo and grade the amount of papilledema in photos using Frisén grading, (2) the CNN model can be adequately trained on a relatively small dataset.

Methods: We used fundus photographs from 165 subjects (330 eyes) in the Idiopathic Intracranial Hypertension Treatment Trial (IIHTT) as input data. Because the IIHTT had few eyes with severe papilledema, we included additional fundus photos from 24 subjects (43 eyes) taken from our clinic for the Frisén grade analysis, and grouped photos showing Frisén grade five papilledema with the Frisén grade four photos. Each photo was labeled according to its Frisén grade (by expert reader), retinal nerve fiber layer thickness (RNFLT), total retinal thickness (TRT), and optic nerve head volume (ONHV) derived from 3D segmentation of corresponding optical coherence tomography images. We trained separate models for quantification of RNFL, TRT, and ONHV, and Frisén grading, using the Densely Connected Convolutional Neural Network “DenseNet161” as the base architecture.

Results: We found a moderate correlation between the true Frisén grades and those predicted by the model (R=0.483, <0.001). We found a strong correlation between the true RNFLT (R=0.793, p<0.001), TRT (R=0.831, p<0.001), and ONHV (R=0.825, <0.001) values and those predicted by the model.

Conclusions: CNN models can identify Frisén grade and provide quantification of OCT-derived RNFLT, TRT, and ONHV values from fundus photographs with moderate success. With supervised learning, it is possible to create reasonable models using relatively small datasets.

TITLE: Does gene expression profile (GEP) and preferentially expressed melanoma antigen (PRAME) predict metastatic risk in all uveal melanoma, including small tumors and iris melanoma?

SESSION TITLE: Tumor - Diagnosis, prognosis, and molecular mechanism

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.C. Oliver, Sue Anschutz-Rogers Eye Center, University of Colorado - Anschutz Medical Campus, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Scott Oliver: Commercial Relationship(s);Code C (Consultant/Contractor):Castle Bioscience;Code F (Financial Support):Roche/Genentech;Code F (Financial Support):Regeneron

ABSTRACT BODY:

Purpose: To determine whether gene expression profile (GEP) and preferentially expressed melanoma antigen (PRAME) predicts metastatic risk in a variety of uveal melanomas. GEP Class 2 and PRAME+ is known to predict increased risk of metastasis in medium-sized choroidal melanoma.

Methods: Retrospective case series of consecutive patients treated at the University of Colorado for uveal melanoma from 2009-2021. Data included tumor height, diameter, location (iris vs choroidal), American Joint Committee on Cancer (AJCC) stage, cytogenetic GEP, PRAME status, last follow-up, and metastasis onset.

Results: 259 uveal melanomas were treated over an 11-year period (51 iris, 208 choroidal). Mean follow-up was 4.6 years, median = 4.2 years. Of these, GEP results were obtained in 227, and PRAME results in 125 (3 GEP technical failures, PRAME available in 2016). No Class 1B tumors (n=39) metastasized over a mean follow-up of 5 years (range = 0.4-11 years). After 60 months of follow up, GEP class 2 predicted increased metastatic risk in all AJCC TNM Stages I-IV (Stage I: GEP2 = 35% vs GEP 1a = 3% vs GEP 1b = 0%; Stage II: GEP2 = 38% vs GEP1a = 5% vs GEP1b = 0%; Stage III: GEP2 = 62% vs GEP 1a = 0% vs GEP1b = none; Stage IV: GEP2 = 100% vs GEP1a/1b = none).

However, irrespective of GEP status, no choroidal tumors <2 mm in height (n=9, GEP2=0) or <8 mm in greatest linear diameter (n=30, GEP2=5), and no iris tumors (n=30, GEP2 = 7), metastasized. No metastases occurred amongst PRAME negative Class 1a/1b tumors (n=51). PRAME positivity predicted more rapid onset of metastasis in Class 2 tumors (11 months PRAME+ vs 20 months PRAME-).

Conclusions: GEP predicts metastatic risk in medium and large choroidal melanoma but does not predict metastatic risk in choroidal tumors <2 mm in height, choroidal tumors <8 mm diameter, or iris melanoma.

ABSTRACT BODY:

Purpose: To determine the severity of age-related macular degeneration (AMD) at first presentation among the Bhutanese patients attending vitreoretinal (VR) clinics and to inform national health policy on the potential benefits of a screening program.

Methods: A retrospective cross-sectional consecutive case series study was conducted on new AMD cases. If a patient presented with asymmetrical AMD, the eye with more severe AMD was considered. If both the eyes had the same severity one eye was chosen randomly. Collection of demographic data and clinical details including diagnostic testing (fundus photography, OCT and fluorescent angiography) and clinical staging were performed.

Results: Of 521 new AMD patients aged 71.9 ± 11.3 years, 306 (58.7%) were males (p=0.005). At their first presentation, 234 patients (44.9%) already had late-stage AMD. Importantly, 69 patients (29.5%), that is half of total neovascular AMD (nAMD) patients, had disciform scars (DS) which were beyond treatment, and 7 (3.0%) had geographic atrophy (GA). Fourteen of nineteen polypoidal choroidal vasculopathy (PCV) patients were younger than 50 years.

Conclusions: Half of total nAMD cases presented as DS not amenable to the treatment. Many potentially treatable patients with nAMD had already lost central vision and were legally blind. Young people with PCV losing vision early in life with longer morbidity-affected life and socio-economic burden was concerning. GA and DS cases need visual rehabilitation to improve their QoL. Incorporating a screening program for AMD with effective health education, and maintaining a national AMD Registry, would potentially lower AMD-related blindness and visual impairment.

ABSTRACT BODY:
Purpose:

Online patient education materials (PEMs) can be difficult for patients to comprehend. With increasing accessibility of online PEMs, it is imperative that healthcare providers understand the quality of such literature so they may direct patients to accurate healthcare information. The purpose of this study is to assess readability, suitability, and accountability of online uveitis PEMs.
Methods: In a cross-sectional analysis, two board-certified ophthalmologists with fellowship training in uveitis analyzed PEMs found on the first ten Google search websites when using the keyword “uveitis”. Readability was assessed using an online calculator; suitability using the Suitability Assessment of Materials (SAM) tool; and accountability using JAMA benchmarks. A review article written for researchers and healthcare professionals was used as a control. Content analysis data were analyzed with the Kruskal-Wallis test and a post hoc Dunn-Bonferroni test. The correlation between accuracy and readability was analyzed using a Spearman correlation test.
Results:

The mean SAM score was 21.05, indicating that the websites were on average adequately suitable to educate patients. The WebMD Uveitis site scored highest with a score of 25.5, while allaboutvision.org scored lowest at 18.0. There was a statistically significant correlation between SAM scores of unique graders ($r=0.8910$, $p<0.0001$).
The average Flesch Reading Ease (FRE) score was 44.0 (95% CI: 34.2, 53.8). The average reading grade score was 11.0 (95% CI: 9.4, 12.6). There was a statistically significant correlation between FRE scores and reading grades ($r= -0.9748$, $p<0.0001$). The difference in average reading grade scores among all websites was statistically significant ($p<0.0001$). The WebMD Uveitis site scored highest on readability.
The average accountability score among the sites was 2.36 out of 4, with statistically significant variation between the sites.
Conclusions: Uveitis websites are only adequately suitable for patient education, and all are above the recommended reading level. We recommend that uveitis specialists be cognizant of the online materials to which they refer their patients. As the average American reads at an eighth grade level, we recommend that authors of online uveitis PEMs use language written at a sixth grade level. This will bridge health literacy gaps and improve access and adherence for all patient populations.

ABSTRACT BODY:

Purpose: There is scant data in the literature on the association of baseline blood pressure (BP) measures and subsequent structural rates of change in glaucoma. We investigated the influence of various baseline BP measures on change rates of macular ganglion cell complex (GCC) thickness in patients with moderate to advanced glaucoma.

Methods: 105 eyes (105 patients) from the Advanced Glaucoma Progression Study with >4 OCT scans and ≥2 years of follow-up were included. Longitudinal rates of GCC change at superpixels and globally were estimated with a Bayesian hierarchical model with both subject and superpixel-level random effects and residuals. The influence of various baseline BP measures on global GCC rates of change were investigated based on prognostic models adjusting for relevant baseline demographic and clinical measures including gender, ethnicity, age, presence of diabetes, intraocular pressure (IOP), central corneal thickness (CCT), axial length (AL), contrast sensitivity, and 10-2 mean deviation (MD). We report one-sided Bayesian p-values defined as the posterior probability that a given regression coefficient is greater than or less than zero with $p<0.025$ used to identify statistical significance.

Results: The average (SD) 10-2 visual field (VF) MD of the study cohort was –8.3 (5.3) dB. The average (SD) follow-up time and number of OCT images per eye were 3.6 (0.44) years and 7.4 (1.1). On multivariable analyses, female gender ($p=0.003$), higher IOP ($p=0.013$), thicker CCT ($p<0.001$), shorter AL ($p=0.001$), higher contrast sensitivity at 12 cycles per degree ($p=0.02$) and better 10-2 MD ($p=0.019$) at baseline predicted faster macular GCC deterioration (Table 1). Adjusted for the above covariates, a lower diastolic BP (DBP) at baseline predicted worse GCC rates of change ($p<0.001$). Parallel multivariable models incorporating various other BP measures at baseline showed that lower diastolic perfusion pressure, lower mean arterial pressure and lower mean arterial perfusion pressure predicted faster GCC rates of change (all p0.001).

Conclusions: Our newly designed hierarchical Bayesian model properly estimates global and regional macular structural rates of change. A decrease in various DBP measures at baseline predicts faster (worse) macular GCC rates of decline in patients with moderate to advanced glaucoma.

ABSTRACT BODY:

Purpose: Xenopus laevis frogs are useful for the study of rhodopsin (RHO) variants due to the ease with which transgenic animals can be generated. RHO knockout X. laevis would provide a useful background for the generation of transgenic animals in which the properties of RHO mutants could be studied in the absence of WT RHO. However, generation of knockouts is complicated by the fact that there are three functional X. laevis RHO genes totaling six alleles. Therefore, we have used a multi-generation approach to develop RHO knockouts, using multiple rounds of CRISPR/Cas9-based gene editing.

Methods: Single-cell X. laevis embryos were injected with Cas9 mRNA and sgRNAs designed to target and edit the X. laevis RHO genes. The resulting animals were raised to maturity and bred to identify animals with null RHO alleles caused by frameshift mutations in the first exon. A second round of editing was used to achieve full knockout of remaining functional RHO alleles by editing the second exon. Rod opsin expression was examined by dot blot, and retinal degeneration and photoreceptor morphology were investigated by confocal microscopy.

Results: By characterizing partial RHO knockout; we found that the RHO.L gene was the highest expressed of the three X. laevis RHO genes, and is responsible for 80% of the rod opsin in a tadpole retina. Partial RHO knockouts did not cause extensive retinal degeneration, but resulted in smaller outer segments. Complete RHO knockouts were generated from a background genotype in which RHO.L and RHO.2.L were knocked out and the RHO.S gene carried an in-frame 12 bp deletion that caused retinal degeneration. Editing of the remaining mutant RHO.S gene reduced retinal degeneration. Photoreceptors with complete RHO knockout as assessed by antibody labeling survived to 14 days, and elaborated morphologically abnormal outer segment-like membranes that lacked RHO.

Conclusions: We have generated X. laevis in which a subset of rod photoreceptors lack RHO expression. Further breeding should result in complete RHO knockout lines. Photoreceptors lacking RHO survive to at least 14 days post-fertilization, and elaborate outer segment-like membranes, a result that differs significantly from previous reports in knockout mice. Further characterization of these membranes may demonstrate the role of RHO in outer segment structure; these animals will also be useful for examining the properties of RHO mutants in the absence of wildtype RHO.

ABSTRACT BODY:

Purpose: Development of predictive biomarkers of response to therapy is a priority for therapeutic optimization in multiple sclerosis (MS). The retina represents an ideal model to investigate effects of disease modifying therapies (DMTs) using non-invasive technologies such as multifocal electroretinography (mfERG) and optical coherence tomography (SD-OCT). After DMTs onset, functional changes may precede structural ones, so neurophysiological retinal response deserves further evaluation. The aim of this study was to analyze changes of first kernel mfERG responses after 12 months of oral teriflunomide treatment (14mg/day) in patients with relapsing-remitting MS (RRMS).

Methods: We conducted a prospective open-label study in RRMS patients starting treatment with oral teriflunomide. Patients were assessed at baseline and after 12 months of follow-up. Baseline exploration consisted of monocular 2.5% low contrast letter acuity (2.5% LCLA), SD-OCT (Spectralis, Heidelberg), mfERG (Reti-Port Science, Roland Consult) and Expanded Disability Status Scale (EDSS). At 12 months of teriflunomide treatment, mfERG exam was repeated. mfERG first kernel responses included N1 wave amplitude and peak time as well as P1 wave amplitude and peak time; results were provided as mfERG sum response and sectorial responses by concentric rings (1-5).

Results: 24 subjects (75% females; mean age of 46.8 years), mild disabled (median EDSS=2.0), were included by March 2018 and completed one year of follow-up. mfERG first kernel responses changed over 12 months showing a mean amplitude increase in N1 (+1.19 nV/deg2 [+17.4%], p=0.048) and P1 (+3.55 nV/deg2 [+20.4%], p=0.006) as well as a decreased peak time in N1 wave (-0.002 ms [-6.7%], p=0.006). Considering sectorial (ring) responses, significant increases were found in N1 amplitude (ring 5) and decreases in peak time (ring 1, ring 3 and ring 4) as well as increases in P1 amplitude (ring 3, ring 4 and ring 5).

Conclusions: After 12 months of teriflunomide oral treatment in RRMS patients, we observed significant improvement in retinal function, as revealed by increased wave amplitudes as well as decreased latencies. Considering lack of a control group, the small sample size and the variability of mfERG explorations, these results require further confirmation.

TITLE: Distinct changes of aquaporins in Connexin 50 knockout and MEK1 transgenic lens epithelial cells

SESSION TITLE: Lens Physiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Xia, W. Lin, C. Ou, T. Zhang, I. Xu, X. Gong, School of Optometry, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure: Chun-hong Xia: Commercial Relationship: Code N (No Commercial Relationship) | William Lin: Commercial Relationship: Code N (No Commercial Relationship) | Chenxi Ou: Commercial Relationship: Code N (No Commercial Relationship) | Tom Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Isaac Xu: Commercial Relationship: Code N (No Commercial Relationship) | Xiaohua Gong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the expression of water channel protein aquaporins (Aqps) in the lens epithelial cells of connexin 50 (Cx50, encoded by Gja8) knockout mice with microphthalmia and MEK1(E) transgenic mice with macrophthalmia. To investigate the mechanism about how Cx50 and MEK1 mediated signal transduction pathways regulate water channels and water transport to affect the lens size and homeostasis.

Methods: Single-cell RNA-sequencing (scRNA-seq) analysis was performed to determine the expression levels of genes including aquaporins in lens epithelial cells of Gja8 knockout (Cx50KO) and MEK1(E) transgenic mice. Aqp1 and Aqp5, two major aquaporins expressed in lens epithelial cells, were further characterized for their protein levels and distributions in vivo and in vitro by using western blot analysis and immunostaining.

Results: Altered Aqp1 and/or Aqp5 protein expressions were observed in the epithelial cells of Cx50KO and MEK1(E) lenses. The scRNA-seq data revealed up-regulated Aqp1 in Cx50KO lens epithelial cells while both Aqp5 and Cx46 remained unchanged. Western blot analysis demonstrated Aqp1 protein level was 2.5-fold increased in the Cx50KO lens epithelial cell homogenates compared to wild-type control samples and was 3-fold increased in cultured Cx50KO lens epithelial cells compared to the wild-type control. Immunostaining further confirmed increased Aqp1 expression in cultured lens epithelial cells. Aqp5 protein levels were insignificantly changed in the Cx50KO lens epithelial cells. In contrast, the Aqp5 level was significantly increased in lens epithelial cells of the MEK1(E) mice while Aqp1 remained unchanged.

Conclusions: Upregulated Aqp1 in Cx50KO lens epithelial cells indicates that both Cx50 and Aqp1 likely play important roles in regulating lens water homeostasis. Increased Aqp1 may result from compensatory mechanism for water transport due to a loss of Cx50. Increased Aqp5 in MEK1(E) lens epithelium likely contributes to enlarged lenses leading to macrophthalmia. These data indicate new regulatory mechanisms of Aqp1 and Aqp5 in water transport of lens epithelial cells in Cx50KO and MEK1(E) lenses.

ABSTRACT BODY:

Purpose: Patients with recessive NR2E3-retinopathy can show enhanced S-cone electroretinogram (ERG) responses. We investigated use of a portable ERG device to record S-cone ERGs with skin electrodes in the clinic or office setting from patients and healthy participants.

Methods: Consecutive patients in the retinal genetics clinic with bi-allelic variants in NR2E3 were recruited as well as healthy controls. ERGs were recorded using a portable device (RETeval with Sensor Strip skin electrodes, LKC technologies, Gaithersburg, MD) following pupil dilation. Stimuli were blue flashes (0.25 and 1.0 photopic cd m-2 s) delivered in the presence of a red background (560 cd m-2). Averages from up to 500 responses were analysed.

Results: Recordings were well tolerated (completed in <5 min per eye). Recordings from 5 healthy participants (3 females) and 5 patients (3 females) were analysed. Mean (SD) age of the healthy participants was 32 (6.8) years (median 30). ERGs from healthy participants were similar with small a-wave amplitudes (<3 and <6 microvolts for the two stimuli respectively), and a-wave peak times of approximately 15-18 ms. B-waves were larger than a-waves, usually with 2 or more peaks. Mean (SD) age of the patients was 44 (8.9) years (median 39). In 3 patients, typical “enhanced” S-cone responses were seen, with simplified waveforms. These patients had larger a-waves (typically >4 and >8 microvolts for the two stimuli) than the healthy participants. The b-waves were of similar size to the a-waves (b: a ratio close to 1) and showed single broad peaks at 50 ms or later (delayed compared to controls). In 1 patient, similar ERGs were recorded from one eye, but the fellow eye, which had a dense brunescent cataract, showed attenuated responses. In the 5^{th} patient, responses were severely attenuated; this patient had widespread retinal degeneration (and attenuated responses on conventional recordings).

Conclusions: The characteristic S-cone waveform features were observable using the portable device and skin electrodes in the majority of the patients tested; these were clearly distinct from the waveform obtained in control participants. S-cone ERGs may be more attenuated by brunescent cataract than standard white light ERGs. The technique may be useful in supporting the diagnosis of NR2E3-associated retinopathy when this is suspected.

ABSTRACT BODY:

Purpose: Cytosolic carboxyl-termini of G-protein coupled receptors (GPCRs) play important roles in dimerization, folding, and membrane transport. Characterized by a small hydrophobic helix and a long flexible tail, C-termini interact with cytosolic partner proteins that couple GPCRs to and modulate signaling pathways. Additionally, GPCRs feature a variety of transport signals within their C-termini, including $E(X)_3LL$, $F(X)_6LL$, and VxPx motifs. However, the mechanism(s) by which these sequences regulate GPCR trafficking remain opaque. Here we examine the functions of C-terminal tail domains in transport of Xenopus laevis rhodopsin to ciliary compartments.

Methods: The role of the rhodopsin C-terminal domains in its localization in the outer segments of photoreceptors was investigated using transgenic X. laevis. Several X. laevis rhodopsin gene mutation and truncation constructs were generated based on multiple sequence alignment and structural information from mammalian rhodopsins and EGFP was appended to the C-termini. Transgenic tadpoles expressing constructs under the Xenopus opsin promoter were generated by REMI and the distribution of gene product was quantified in rods using confocal microscopy.

Results: Contrary to previous reports, truncation of the rhodopsin C-terminus at residue 310 resulted in significant mislocalization of rhodopsin to the photoreceptor cell body, showing that the C-terminus is indeed essential for proper outer segment localization. Addition of VxPx to this truncated construct did not rescue outer segment localization. A previous study of zebrafish rhodopsin showed that methionine 317 (M317), which is conserved across all vertebrate species examined to date except Xenopus which possesses a leucine at this site (L317), results in partial mislocalization of the protein to the cell body. This was completely mitigated by replacing M317 with L. We show here that the reciprocal experiment, generating L317M mutation in Xenopus rhodopsin, results in its partial mislocalization.

Conclusions: Our results show that residue 317 and the VxPx motif are essential for efficient rhodopsin trafficking. L317 allows the most efficient rhodopsin localization to rod outer segments. Remarkably, vertebrates possess rhodopsins with the inefficient M317 and, thus, their rods have chronic, low-level rhodopsin mislocalization.

ABSTRACT BODY:

Purpose: AAV-mediated gene therapy is an attractive option for the treatment of inherited retinal dystrophies. Retinitis Pigmentosa caused by mutations in PDE6B are potentially good candidates for such treatment, and different animal models are available for proof of concept and preclinical investigation. Among them, the rd10 mouse model, which displays a complete deficiency in PDE6B activity, exhibits rapid rod photoreceptor degeneration followed by secondary cone cell death. In this model we evaluated the biological activity of clinical-grade recombinant AAV2/5 vector batches encoding the human PDE6B cDNA (hPDE6B) under transcriptional control of a RK (Rhodopsin Kinase) promoter.

Methods: rd10 mice were reared in dark environment until postnatal (PN) day 28. A volume of 1uL AAV vectors was injected subretinally at PN14 in a single eye. Two cohorts of 6 animals each were treated with two different vector doses: 1.6 x 10e9 and 5 x 10e9 vg/eye. The presence of a bleb after subretinal injection was controlled by OCT examination. At PN35, optical coherence tomographic examination (OCT) and electroretinogram (ERG) were performed. At PN60, OCT, ERG and quantitative optometric response (qOMR) were performed. Mice were sacrificed at PN65, and treated and control eyes were fixed and processed for morphological evaluation as well as immunohistochemistry (IHC).

Results: In the high-dose group, a statistically significant improvement of retinal response to light stimulus (ERG and qOMR) was observed in the treated eye at the earliest time point of evaluation (PN35) and the correction was maintained until sacrifice. Retinal morphology evaluated by OCT was preserved and IHC revealed higher survival of photoreceptors in the treated eye compared to the contralateral eye. In the low-dose group, no statistically significant difference in ERG and qOMR was observed between treated and untreated eyes. However, significant preservation of photoreceptors in treated eyes was observed, mainly at the earliest time point and retinal morphology was partially preserved.

Conclusions: AAV-mediated hPDE6B gene therapy is a valid strategy to prevent photoreceptor degeneration in a PDE6B-related RP model, which further supports the relevance of this approach in the clinic. Therapeutic threshold, however, appears as a critical parameter to achieve clinical benefit.

ABSTRACT BODY:

Purpose: To evaluate the association of steady-state pattern electroretinogram (PERG) with standard automated perimetry (SAP) and optical coherence tomography (OCT) parameters in glaucoma.

Methods: This was a cross-sectional evaluation of glaucoma patients and normal controls included in an observational cohort study. Each patient underwent 24-2 SAP, OCT, and PERG testing with the Diopsys NOVA PERG contrast sensitivity protocol (ConSen protocol) within 7 days. The following PERG parameters were analyzed: MagnitudeD, corresponding to the amplitude of the average signal, and MagD/Mag Ratio, the consistency of the response. For both parameters, lower values indicate an increased likelihood of visual dysfunction. The parameters were tested at high (Hc) and low contrast (Lc). Tests with excessive artifacts or low signal quality were excluded. Linear mixed models nested at the patient and eye levels were used to evaluate the relationship between PERG parameters with SAP MD and RNFL thickness and R^2 was used to measure the strength of the relationship.

Results: The study included 85 visits of 77 eyes of 40 subjects with mean age of 67.5±9.4 years. Eyes had an average SAP MD of -4.97±6.49dB and RNFL thickness of 74.1±18.0µm, with 18% of eyes classified as normal and 82% as glaucoma. The Lc MagnitudeD was 0.014 lower for each 1 MD dB lower (R^2 =0.41; P = 0.001) and 0.040 lower for each 10 µm thinner RNFL (R^2=0.38; P = 0.011), after adjustment for age and gender. For MagD/Mag ratio, RNFL thickness, but not SAP MD, was significantly associated with MagD/Mag ratio at Lc, with 0.03 lower value for each 10µm thinner RNFL (R^2 = 0.39; P = 0.021). Neither RNFL nor SAP MD were significantly associated with PERG Hc parameters in multivariable analyses.

Conclusions: Low contrast stead-state PERG parameters were significantly associated with structural and functional metrics in glaucoma.

ABSTRACT BODY:

Purpose: To identify a transcriptomic profile in undifferentiated and early differentiating hiPSCs that would predict a given cell line's propensity to generate retinal cells.

Methods: Human iPSCs generated via Sendai virus were validated by scorecard and karyotype analysis prior to differentiation. hiPSC lines were differentiated toward a retinal cell lineage using a stepwise 3D differentiation protocol. RNA was isolated from days 0 and 7 of differentiation and subjected to RNA-sequencing. Transcriptome profiles were determined and validated from a total of 15 independent donors with low vs. high retinal differentiation capacity. Findings were validated in a masked fashion using an additional 16 cell lines.

Results: At 0 and 7 days post-differentiation, cultures were evaluated using RNAseq. Retinal structures were quantified for retinal phenotype microscopically at 16 and 20 days of differentiation. Analysis was focused on identifying genes differentially expressed between good retinal producers (40-80% of organoids showing a retinal phenotype, n=8) and poor retinal producers (<30% of organoids showing retinal phenotype, n =7). Good and poor retinal producer populations demonstrated remarkable gene expression similarity across all lines prior to differentiation (day 0), which was validated via qPCR-based expression analysis. By just 7 days of differentiation, when embryoid bodies all looked the same, significant differences in gene expression could be detected between good vs poor retinal producers. Ingenuity pathway analysis revealed perturbations in both OCT4 and SOX2 effector gene expression, with expression of many of the factors being maintained in poor producers indicating delayed suppression of pluripotency. This pattern of altered genes expression was validated in an additional 16 cell lines in a masked fashion.

Conclusions: There were no discernable differences in pluripotency or other gene expression in undifferentiated hiPSCs. By day 7 of differentiation, a signature gene expression profile, which predicts a given hiPSC line's propensity to generate retinal cells upon further differentiation, could be detected. Specifically, 25+ genes that are differentially expressed between days 0 and day 7 of differentiation were identified. Modulation of these key factors may assist in enhancement of retinal differentiation.

ABSTRACT BODY:

Purpose: Significant challenges with current techniques to reproducibly grow RPE monolayers remain, and it is unclear which models are the most physiologically relevant. Here, we studied various conditions of long-term primary human RPE (hRPE) culture to optimize techniques for reproducible development of functional, polarized RPE monolayers.

Methods: Early passage (p3-5) hRPE cells (Lonza) were seeded at densities of 0.5, 1, and 2 x 10^5 cells per cm^2 (n=2-4). For media, hRPE were initially fed RPE cell Growth Medium Bullet Kit (RtEGM, Lonza) or RPE culture medium (RPECM, alpha-MEM plus 1% N1 Supplement, 1% Glutamine-Penicillin-Streptomycin, 1% non-essential amino acids, 250 mg/L taurine, 20 mg/L hydrocortisone, 0.013 mg/L triiodo-thyronine) with 1, 5, 10% FBS on transwell plates coated with human fibronectin (2 µg/cm^2). RPE cultures with RtEGM media were either left with same media type or switched to RPECM (1, 5, 10% FBS) at 2d while cells with RPECM were kept in that media. TER, ZO-1 immunofluorescence, and pigmentation were evaluated at various time-points (14d/21d/28d). Statistical analyses were performed with ANOVA and Mann-Whitney U test.

Results: Long-term hRPE cultures with high-density seeding of hRPE isolates (2 x 10^5) yielded the most tightly packed hexagonal arrays with the peak TER values ($P<0.05$) by 21d. Cultures seeded in RtEGM and then switched to 1%, 5%, and 10% FBS in RPECM demonstrated significantly increased TER measurement (> 400 Ω cm^2, $P<0.05$) compared with RtEGM (250 – 350 Ω cm^2) or RPECM (20–50 Ω cm^2). Cultures seeded in RtEGM initially and then switched to RPECM at 2d reproducibly formed monolayers with increased pigmentation (3x) compared to cultures in RPE culture media alone.

Conclusions: Establishing reproducible long-term primary hRPE cultures is critical to experimental designs that propose to study RPE biology. Our data provide an optimized technique for long-term culture of hRPE with high density seeding in growth factor enriched media (RtEGM) followed by feeding with RPECM at 2d. Tight junctions, TER and pigmentation are significantly increased, and monolayers are well-formed by 21d. The utilization of these methods will greatly assist others in the field that are performing long-term RPE culture to achieve reliable models of RPE cell biology and AMD-like RPE degeneration in vitro.

ABSTRACT BODY:

Purpose: To investigate whether retinal vessel density (VD) of the superficial (SCP), intermediate (ICP) or deep (DCP) capillary plexuses is associated with the risk of progression to proliferative DR (PDR) in eyes with moderate to severe nonproliferative DR (NPDR).

Methods: Treatment-naïve eyes with moderate to severe NPDR within the ETDRS fields on ultrawide field photographs were imaged using 3x3 mm scans on OCTA (AngioVue). DR severity was graded by certified graders. OCTA images were exported to ImageJ (ver 1.51, National Institutes of Health) to manually calculate VD of the parafovea. Clinical data, including treatment history and demographics were reviewed and recorded on standardized forms.

Results: The study group was 75 treatment-naive eyes (70 subjects) with moderate (N=37), moderately severe (N=20) or severe (N=18) NPDR at baseline and a mean follow-up of 2.9±1.3 yrs. Mean±SD age was 49.4±13.4 yrs, 47.2% were female and 61.1% had type 1 diabetes with 26.1±11.8 yrs duration. Eleven eyes, all with baseline severe NPDR, developed PDR within 1.3±1.2 yrs. In the whole cohort, no significant difference was found in mean baseline OCTA SCP, ICP or DCP VD between eyes with or without 2 or more step DR severity worsening or between eyes that did and did not progress to PDR. Time to event analyses of the subgroup with moderately severe or severe NPDR found eyes with decreased DCP VD had higher risk of PDR [point estimate (95% CI): 1.43 (1.1-15.3), p=0.03]. In the subgroup with baseline severe NPDR, time to PDR onset was significantly faster in eyes with increased SCP [1.43 (1.1-15.3), p=0.03], decreased ICP [-0.97 (0.2-0.9), p=0.04] or decreased DCP [-2.51 (0.1-0.6), p=0.02] VD, even after adjusting for age, signal strength index and spherical equivalent.

Conclusions: Subgroup analyses from this study suggest that retinal capillary plexus VD is potentially associated with risk of PDR onset in eyes with moderately severe to severe NPDR. Findings from this cohort are consistent with the hypothesis that eyes with lower DCP, and possibly ICP VD may have faster onset of PDR. The association of higher PDR risk with higher SCP VD could be due to greater SCP perfusion from vascular shunting and capillary remodeling that precedes neovascularization, but additional studies are needed to validate and address this issue.

ABSTRACT BODY:

Purpose: Activated dendritic cells (aDCs) have recently been identified as potential biomarkers indicating the presence of a systemic auto-immune disease in individuals with dry eye (DE). However, their evaluation with in-vivo confocal microscopy (IVCM) is relatively subjective. Therefore, there is a need for a standardized identification method of aDCs to improve generalizability. Our aim was to validate an algorithm that automatically identifies and quantifies aDCs using IVCM images of the central cornea.

Methods: A retrospective analysis of IVCM images obtained from individuals seen at the eye clinic at the Miami Veterans Affairs Hospital was performed. Images from individuals with corneal scarring were excluded due to potential confounding. Artificial intelligence was utilized through the use of an automated aDC counter which was developed using transfer learning with IVCM images. IVCM images used in the development of this algorithm were acquired prior to the start date of this study and did not include any of the same patients. ADCs were manually quantified based on morphology by reviewers that were masked to the algorithm findings, and intra-class correlation (ICC) was used to compare automated and manual counts. Algorithm accuracy was defined as aDC counts within 1 cell compared to manual quantification.

Results: A total of 193 non-overlapping IVCM images from 110 individuals were included. The mean age of individuals included in the study was 55.5±18.4 years; 70.0% were male, 58.2% self-identified as White and 24.5% as Hispanic. There was no statistically significant difference in the mean aDC count between automated and manual quantifications (1.06±1.82 cells/image vs 1.21±1.98 cells/image, p=0.47). The algorithm identified a total of 207 aDCs within the dataset, out of which 184 were manually verified as aDCs. The automated algorithm performed the aDCs count with 87% accuracy and an ICC of 83% ($p<0.01$).

Conclusions: The number of aDCs in the central cornea can be successfully estimated with the use of artificial intelligence with comparable results to manual quantification. Further assessment is needed before the widespread clinical implementation of an automated aDC counter.

ABSTRACT BODY:

Purpose: A significant number of chronic GVHD patients suffer from pathological changes affecting conjunctiva including pseudomembranous conjunctivitis, symblepharon, fornix shortening and bulbar subepithelial conjunctival fibrosis. The purpose of the present study was to investigate the mechanisms underlying GVHD-associated conjunctival fibrosis.

Methods: A mouse model of major histocompatibility-matched and minor histocompatibility-mismatched allogeneic transplantation from B10.D2 donors to BALB/c recipients was used to induce ocular GVHD. Control group was BALB/c to BALB/c syngeneic transplantation. Eyes were harvested at 2 and 4 weeks after the transplant. The tissue sections were stained for alpha-smooth muscle actin (α-SMA) to detect myofibroblast formation as a marker for fibrosis. Nanostring technology based spatial immunostaining was performed for macrophages markers. Gene expression quantification and immunostaining was also performed for profibrotic mediators including TGF-β1, PDGF, and components of renin angiotensin system (RAS).

Results: Prominent α-SMA staining was observed in the bulbar orbital conjunctiva of mice that received allogeneic bone marrow transplantation. Immunophenotyping revealed a concomitant increase in macrophage markers and profibrotic M2 macrophage markers in the conjunctiva of these mice. Allogenic transplantation also caused a 2- to 10-fold increase in the gene expression and protein expression of TGF-β1, PDGF, angiotensinogen and angiotensin converting enzyme in the conjunctiva of these mice.

Conclusions: Results of the present study demonstrate that GVHD-associated conjunctival fibrosis is accompanied by myofibroblast formation, influx of macrophages and an increase in profibrotic mediators.

TITLE: DLK is Necessary for Retinal Ganglion Cell Axonal Regeneration in Xenopus laevis
SESSION TITLE: Neuroprotection and Neuroregeneration
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L. Fague, University of California Davis, Davis, California, UNITED STATES|N. Marsh-Armstrong, University of California Davis School of Medicine, Sacramento, California, UNITED STATES|
Commercial Relationships Disclosure: Lindsay Fague: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Marsh-Armstrong: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Unlike mammalian species, Xenopus laevis can regenerate their retinal ganglion cell (RGC) axons after optic nerve injury. The molecular mechanisms enabling this remain unknown. We performed a pilot CRISPR-screen using a novel moderate-throughput tadpole optic nerve crush (ONC) assay to identify genes necessary for axonal regrowth. Among the genes targeted was Dual leucine zipper kinase (Dlk; i.e. Map3k12).
Methods: For Dlk knockout (KO) line creation, sgRNAs targeting Dlk were injected into eggs within 30 minutes of fertilization. Dlk KO tadpoles were subjected to ONC using bevelled 50-75 um glass needles mounted on micromanipulators at 8 days post-fertilization. Optic nerves and tecta were live imaged over the next 7 days using a Leica fluorescent stereomicroscope. For retrograde tracing, Mitotracker-soaked gelfoam was inserted into the optic tecta at 6 days post-ONC and eyes were dissected out 24 hours later. Degree of reinnervation was assessed from the live imaging data. Phosphorylation of Jun (pJun) and source of tectal innervating axons were assessed in immunolabeled cryosections imaged using a Leica Dragonfly confocal microscope. Custom IPlab scripts were used for all quantifications. All animals were genotyped via sequencing and TIDE analysis.
Results: Dlk full KO animals had 27% of the tectal innnervation seen in wildtype animals 6 days post-ONC, and animals with only 2 copies of an in-frame deletion, Dlk(d56-58), had 60% (X. laevis is allotetraploid with 4 copies of Dlk). In wildtype animals, innervation post-ONC was mainly from central (crushed) RGCs; however, in Dlk KOs, tectal innervation was limited to the most peripheral (newly born) RGCs. ONC significantly increased nuclear pJun selectively in RGCs 2d post-ONC, a response blunted but not absent (40% less than control retinas) in Dlk KOs.
Conclusions: Dlk specifically affects RGC axonal regeneration in a regeneration-capable species. Our assay shows that while new axons are born after injury, most tectal innervation post-ONC comes from preexisting axons, and this innervation is selectively inhibited in the Dlk KO animals. Findings are largely consistent with other literature placing Dlk in a pathway conveying an axonal injury signal to the soma. However, the pJun results show that RGC soma sense axonal injury independent of Dlk. We believe that genes downstream of Dlk in X. laevis offer much promise to promote RGC axonal regeneration in mammals.

TITLE: Tractional retinal detachment repair: a retrospective study to improve prognostication
SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: D.T. Szynkarski, R. Cortez, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|D.T. Szynkarski, S. Trejo Corona, R. Cortez, S.B. Patel, T. Wong, D. Garcia, J. Major, C.C. Wykoff, Retina Consultants of Texas, Houston, Texas, UNITED STATES|
Commercial Relationships Disclosure: David Szynkarski: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Trejo Corona: Commercial Relationship: Code N (No Commercial Relationship) | Ray Cortez: Commercial Relationship: Code N (No Commercial Relationship) | Sagar Patel: Commercial Relationship: Code N (No Commercial Relationship) | Tien Wong: Commercial Relationship: Code N (No Commercial Relationship) | David Garcia: Commercial Relationship: Code N (No Commercial Relationship) | James Major: Commercial Relationship: Code N (No Commercial Relationship) | Charles Wykoff: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:
Purpose: Tractional retinal detachment (TRD), the separation of the neurosensory retina from the retinal pigment epithelium (RPE), is a common consequence of proliferative diabetic retinopathy (PDR). TRD cases are complex and have varied surgical outcomes. In this study, we performed a retrospective observational study to observe trends in TRD surgical outcomes with the goal of aiding in preoperative prognostication.
Methods:

Medical records of 193 patients with concurrent diagnoses of PDR and TRD requiring surgery between December 2016 and September 2021 were reviewed. Macula involvement and vitreous hemorrhage at presentation as well as visual acuity (VA) prior to, 1 month after, and 6 months after surgery were recorded. LogMAR VA was used to calculate the mean, standard deviation, and two-tailed t-tests.
Results: Two hundred and seventeen eyes from 193 subjects were studied (n = 217). Mean VA was 1.66 logMAR (~20/900) preoperatively, 1.54 logMAR (~20/700) 1-month post-operatively, and 1.40 logMAR (~20/500) 6-months postoperatively. Of those with a preoperative VA of 20/200 or less, 31% achieved a postoperative VA of 20/70 or better, 12% fell between 20/70 and 20/200, and 57% did not exceed 20/200 at 6-month follow up. Seventy-four percent of TRDs involved the macula. A statistically significant difference in preoperative VA between the macula involving and macula sparing groups ($p > 0.15$) was not observed. However, at 6-month follow-up, 63% of eyes with macula sparing TRDs regained VA of at least 20/70 compared to only 37% of eyes with macula involving TRDs. This suggests that preoperative VA and presence of macula involvement are independent factors that can help prognosticate VA outcome. However, eyes without vitreous hemorrhage (VH) and with preoperative VA of 20/200 or worse were less likely to improve to 20/70 or better versus eyes with VH prior to surgery (14% vs 39%). Therefore, presence of VH may be a confounding factor to consider when using preoperative VA as a prognostication tool.
Conclusions: TRDs are challenging to repair and have a wide array of outcomes, making preoperative prognosis difficult. This study quantifies the prognostic advantage conferred by a preoperative VA of 20/200 or better and by the presence of macula sparing disease. It also demonstrates the effectiveness of TRD repair as a whole. Further analysis will be aimed at elucidating the presence of other confounding variables.

ABSTRACT BODY:

Purpose: In patients with diabetes, retinal capillary non-perfusion often precedes ophthalmoscopically visible lesions such as microaneurysms and dot hemorrhages. Signs of capillary perfusion loss have been detected in children and adolescents with a duration of diabetes shorter than 10 years. The purpose of this ongoing study is to map capillary perfusion loss in type I diabetes from early childhood.

Methods: This observational study has currently enrolled 50 participants with type I diabetes and 31 age-matched healthy control subjects. Patient age range was 6-32 (mean 15) years and diabetes duration 14.5-17.5 years (n = 8), 9-11.5 years (n = 14), 4.5-6 years (n = 17), and 0-4 months (n = 11). In healthy controls, the age range was 8-34 (mean 16) years. Exclusion criteria were significant chronic systemic disease other than diabetes and ocular disease other than diabetic retinopathy. Examinations included 3x3 mm macular optical coherence tomography angiography scans (OCTA; Topcon Triton) and fundus photography (Optos). Capillary densities of four different ETDRS grid sectors of the macula were calculated using proprietary software (Topcon ImageNet6) (fig. 1).

Results: Of 50 patients with type I diabetes, seven had very mild and two had mild non-proliferative diabetic retinopathy. Superficial capillary plexus density in patients with diabetes duration 14.5-17.5 years was 44.7 % (mean of temporal sector), compared to patients with shorter diabetes duration and healthy subjects (mean temporal sector densities 47.8 % and 47.6 %, respectively). The numerical deficit in the grid sectors decreased in the order nasal, inferior, temporal, superior. Three of the eight patients with a density below 44.7 % had fundus photographic retinopathy, the rest did not.

Conclusions: Preliminary data from this observational study of patients with type I diabetes suggest that decreased macular capillary density can be detected after a diabetes duration of 15 years and before it can be seen on color fundus photographs. Full enrolment and longer observation time may provide more definite information about these issues.

TITLE: Clearing up the causes of corneal clouding in aniridia-related keratopathy

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.K. Scavuzzo, J.D. Lauderdale, Cellular Biology, University of Georgia, Athens, Georgia, UNITED STATES|D.K. Scavuzzo, Optometry, University of Pikeville, Pikeville, Kentucky, UNITED STATES|

Commercial Relationships Disclosure: Diana Scavuzzo: Commercial Relationship: Code N (No Commercial Relationship) | James Lauderdale: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aniridia often results in progressive corneal clouding termed aniridia-related keratopathy (ARK), but the causes of this corneal clouding are not well understood. The current study investigates three hypotheses as to the causes of corneal clouding in ARK: decreased ocular surface integrity, increased conjunctivalization, and activation of the pro-fibrotic response. Clinical, histological, and immunofluorescent evaluations were performed in the $Pax6^{+/-}$ mouse model Small Eye (Sey).

Methods: Wild-type ($Pax6^{+/+}$) and Sey ($Pax6^{+/-}$) corneas were assessed at two time points: 17-19 weeks old (mild ARK symptoms) (N=10 wild type, 6 Sey) and 40+ weeks old (severe ARK symptoms)(N=6 wild type, 6 Sey). Clinical assessment was performed by corneal clarity and ocular surface integrity scoring via fluorescein uptake.Histological assessment was performed on one eye of each mouse via paraffin sectioning, hematoxylin and eosin staining and periodic acid-schiff (PAS) staining to assess conjunctivalization. Two-way analysis of variance was performed for statistical analysis of PAS staining. Immunofluorescent evaluation was performed on one eye of each mouse via cryosectioning, blocking with 0.2% Bovine Serum Albumin and 5% goat serum, and incubating in 1:1000 dilution primary antibodies a-SMA (myfibroblast marker) and collagen type III (marker of fibrotic wound healing response).

Results: Consistent with our hypothesis, as corneal clarity decreased, ocular surface integrity decreased in Sey mice at each time point. Two way ANOVA showed average number of conjunctivalization in mouse corneas differed between wild-type and Sey mice ($df=1$, $F=10.367$, $p<0.01$). Conjunctivalization did not differ between 17-19 week old and 40+ week old mice ($df=1$, $F=3.163$, $p=0.106$). As corneal clarity decreased in 40+ week old Sey mice as compared to 17-19 week old Sey and wild type, this finding was contrary to our hypothesis. Our hypothesis of activation of the pro-fibrotic response was confirmed through immunofluorescent evaluation, with expression of a-SMA and collagen type III in the anterior stroma as corneal clouding progressed.

Conclusions: We have furthered the hypotheses of ocular surface integrity and activation of the pro-fibrotic response contributing to progressive corneal clouding in ARK, while our hypothesis of increased conjunctivalization was not supported. The findings of pro-fibrosis could open pathways for potential treatment modalities.

ABSTRACT BODY:

Purpose: We have previously shown that peripheral blood mononuclear cells (PBMC) from glaucoma patients can degrade retinal ganglion cells (RGC) in immune deficient mice. Here we correlate the RGC loss in mice with ophthalmic metrics of donating patient.

Methods: Blood samples were obtained from primary open angle glaucoma (POAG) patients without regard to disease state or rate of vision loss (n=20). In addition, samples were obtained from non-glaucomatous controls (n=10). Exclusion criteria were other retinal diseases (except AMD) autoimmune disease or neurodegenerative diseases. PBMC were isolated from these samples and transferred into immune deficient NOD/scid gamma (NSG) mice by intraperitoneal injection. Each mouse received PBMC from one donor only, creating an immunologic 'avatar' of the patient. After transfer mouse eyes received a microbead injection calibrated to cause mild, transient elevation of intraocular pressure (IOP). 50 days after PBMC transfer, RGC density was determined in retinal flat mounts using cresyl violet staining. Data were compared to clinical findings observed in the patients.

Results: Transfer of human PBMC did not cause significant side effects. However, retinas of mice having received PBMC from POAG donors displayed significantly fewer RGC than those having received PBMC from controls (255±64.8 RGC/field vs. 341±131 RGC/field, p=0.027) in central area. Among donors with POAG, PBMC of those with more advanced disease caused less damage to the recipients' RGC than PBMC with less advanced disease. Avatars of donors with a ganglion cell layer (GCL) thickness above the median displayed 197±60.9 RGC/field whereas those with GCL thickness below the median contained 282 ±75 RGC/field (p:0.017). Likewise, avatar mice of donors with visual field loss above the median displayed 296±62 RGC/field, significantly more than those having received PBMC from donors with more advanced field loss (204±84 RGC/field, p=0.045). Other clinical parameters, including maximum or average IOP of the patient, do not appear to be correlated with RGC loss in recipient mice.

Conclusions: Conclusions: These findings confirm that transfer of PBMC obtained from glaucoma patients causes more damage to RGC in NSG mice than those of controls. Our data also indicate that immune reactions may be more pronounced in POAG patents with moderate disease than in those with advanced disease.

TITLE: Development of convolutional neural networks for automated image gradeability assessment in a diabetic retinopathy screening program

SESSION TITLE: AI in the Retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Bryan, P. Bryar, R. Mirza, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: John Bryan: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bryar: Commercial Relationship: Code N (No Commercial Relationship) | Rukhsana Mirza: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The standard of care for diabetic patients is to have an eye exam or retinal imaging to assess for diabetic retinopathy (DR). In recent years there has been increased interest in developing artificial intelligence (AI) tools for optimizing screening of ocular imaging. In this retrospective study, we developed an AI-based approach for assessing the gradeability of images in a DR screening program.

Methods: Non-mydriatic retinal images were gathered from diabetic patients who underwent imaging during a primary care or endocrinology visit at Northwestern Medicine from September 1, 2017 to June 1, 2021. The Eidon SLO Confocal Scanner (Centervue Inc., Fremont, CA) was used. Images were interpreted by Northwestern ophthalmologists for gradeability, presence and severity of DR, and the presence of non-DR pathologies. Following image interpretation, the TensorFlow and Keras platforms were utilized to train convolutional neural networks (CNNs) to assess image gradeability. Images were divided into training, test, and validation sets. Inception V3 and Xception V1 network architectures were evaluated, with network weights preinitialized using a network trained on ImageNet, a set of 14 million images used for computer vision research. Networks built with different combinations of hyperparameters (learning rate (LR), dropout rate (DropR), and dense layer output dimensionality (DLOD)) were compared by validation set performance.

Results: 1550 non-mydriatic retinal images from 575 patients (55% female, median age 58) were analyzed in this study. Northwestern ophthalmologists deemed 23.6% (366/1550) of these images to be ungradable. Of gradable images, ophthalmologists found 20.4% (241/1184) had DR of varying degrees and 26.9% (319/1184) had non-DR ocular pathology.

Comparing CNNs, validation set performance was maximized with (LR = 0.001, DropR = 0.3, DLOD = 256) for the Inception V3 network and (LR = 0.0001, DropR = 0.3, DLOD = 256) for the Xception V1 network. On the test set the Inception V3 network exhibited 87.5% accuracy (AUC 0.935) and the Xception V1 network exhibited 86.41% accuracy (AUC 0.929).

Conclusions: It is feasible to develop CNNs that can assess the gradeability of non-mydriatic retinal images with a high degree of accuracy. AI-based frameworks such as these may enable more efficient identification of ungradable images in DR screening programs.

ABSTRACT BODY:
Purpose: Trainee wellness and burnout continue to emerge as an ACGME area of focus for resident training. Maslach, et al. define burnout syndrome as a depleted state characterized by emotional exhaustion, depersonalization, and a decreased sense of accomplishment. Ophthalmology residency has its own unique triggers that can lead to burnout, the most stressful of which taking weekend call.

Through knowledge-transfer exercises that impart specific stress-reduction strategies such as breath-control exercises, expressing gratitude, and identifying positive affirmations, we hope to modify Ophthalmology residents' attitudes toward stress and wellness.
Methods: This prospective study was reviewed by our institutional IRB and awarded an exempt status. The aforementioned knowledge transfer exercises were reviewed with first-year Ophthalmology residents through online lectures and discussion sessions in October 2020. Residents were encouraged to use these strategies to combat the stress of taking weekend call. The effectiveness of these strategies was quantified using pre- and post- call questionnaires which measured self-efficacy, stress regulation, and solution-mindedness.
Results: These questionnaires had a response rate of 87% with a completion rate of 91%. In our cohort of first-year Ophthalmology residents, breath-control exercises were identified as the most effective strategy for mitigating the stress of taking weekend call. Breath control exercises were both the most utilized and most effective strategy for in improving self-efficacy, stress regulation, and solution mindedness. Residents responded "moderately true" or "exactly true" in response to breathwork effectiveness questions in 73.9%, 82.9%, and 71.9% of cases respectively. Final biostatistical analysis is pending and will provide further insights.
Conclusions: Teaching ophthalmology residents strategies to combat stress is an effective tool for promoting wellness and preventing physician burnout.

ABSTRACT BODY:

Purpose: To report the utility of St. Thomas' Hospital Cataract Risk Stratification Tool (Cat-12) in femtosecond laser assisted cataract surgery (FLACS) research and NHS patients undergoing conventional cataract surgery. Trainees, fellows and consultants were selected into 3 groups to keep complications within national standards for all surgeon grades.

Methods: 609 patients, 338 female (mean age 71y) and 271 male (mean age 69y) treated between November 2017-February 2018 were included. 330 underwent conventional surgery, 279 underwent FLACS. Cat-12 stratifies risk into: low (score<3), moderate (3-6), and high risk (>6). Surgeon selection was any grade for low risk; fellows/ consultants for moderate risk, consultants for high risk cases. Accurate completion of Cat-12 was examined, all complications by surgeon grade, and risk category analysed.

Results: Cat-12 was completed in 98% of all participants. 68% were considered routine (<3 Cat-12 score). 22.5% of these were performed by trainees, due to consultants recruiting routine cases for FLACS research. For moderate risk cases, 40% were performed by trainees/fellows, 60% by consultants. Similarly, 37% high risk cases were performed by trainees/fellows (9%,28%). Our trainees and fellows were exposed to higher complexity cases, with adequate supervision based on Cat-12 stratification. PCR rates were 1.2% in low risk, 1.5% moderate risk and 2.2% in high risk groups, better than UK published standards for cataract surgery. There were more complications in the conventional surgery group (n=22) compared to FLACS (n=9), most commonly iris trauma (n=8) followed by anterior chamber tears (5 manual capsulorhexis, 3 rhexis tags following FLACS). There were no cases of endophthalmitis, one case of suprachoroidal haemorrhage in a high risk case, which was performed by a consultant, with a good final outcome.

Conclusions: Using the Cat-12 Tool, we identified the level of supervision required, and grade of surgeon needed to deliver safe, effective surgery. Trainees and fellows performed higher complexity cases (medium and high risk, while routine cases were recruited into research). We report low complication rates when juniors were supervised by the correct level of surgeon selected at the time of listing. There was no difference in complication rates between our junior and senior surgeons.

ABSTRACT BODY:

Purpose: To develop approaches to restore accommodation, research has focused on studying the age-related changes leading to presbyopia. Prior studies have quantified changes in lens shape in response to static accommodative demands, but there is limited data on the relation between lens shape and objective accommodation, and the dynamics of lens shape changes. The goal of this study is to quantify the age-dependence of the optical and biometric accommodative response using a custom-built combined autorefractor and OCT system.

Methods: Accommodative responses of 12 subjects aged 20 to 66 years (mean spherical equivalent refraction −1.67 ± 2.30 D, range -6.25 to 1.75 D) were measured using a device that combined a fixation target providing a controlled ramp accommodation stimulus, wavefront-based autorefractor, and an extended-depth OCT system that acquires images of the anterior segment and lens. Subjects were presented with a 12 D ramp stimulus at a speed of 0.5 D/s. Wavefront measurements and cross-sectional OCT images were acquired sequentially in real-time during the ramp at 33 Hz and 4.7 frames/s, respectively. Three runs were performed on each subject. Lens thickness was quantified from the OCT images using a semi-automatic segmentation software. The following parameters were quantified versus age: maximal accommodation, lens thickness change, accommodation response vs stimulus, lens thickness per D stimulus, and the relation between lens thickness change and optical accommodative response.

Results: Refraction and lens thickness varied linearly with stimulus. The optical response to a given stimulus decreased with age at a rate of 0.023 D/D/year. (Figure 1C) There was no statistically significant age-dependence of the change in lens thickness per Diopter of accommodative response in pre-presbyopic eyes (Age <50 years, average: 0.032 mm/D). (Figure 1D)

Conclusions: The decrease in accommodative gain (response/stimulus) combined with constancy of the lens thickness per Diopter response lends further support to the theory that attributes presbyopia to age-related changes in the ability of the lens to change shape.

ABSTRACT BODY:

Purpose: Melanopsin (Opsin 4) is a photopigment expressed in the retinal ganglion cells and is critical for non-image forming vision. The goal of this study was to determine the role of melanopsin signaling for maintaining retinal integrity and function.

Methods: $Opn4^{-/-}$ and wild-type littermate control animals were longitudinally assessed from 3 months (M) to 14M using optical coherence tomography (OCT) based measurements. OCT findings were validated using immunofluorescence and protein blots. Transcriptomic (RNA Seq) and proteomic analyses of the retina were carried out at 4M and 12M. Rates of degradation of phagosomes and the diurnal exposure of phosphatidylserine was measured using anti-rhodopsin and Annexin A5.

Results: Loss of melanopsin results in late-onset degeneration of the retina with spatiotemporal differences in the progression of the photoreceptor degeneration. For example, medium opsin (M-opsin) is reduced at 12M in $Opn4^{-/-}$ retinas, with a severe reduction in the dorsal region of the retina. A similar dorsal-ventral gradient in outer nuclear layer thickness was detected. Electroretinography (ERG) analysis failed to detect any changes in the rod photoreceptor responses but cone responses were significantly reduced. A morphometric analysis of the RPE indicates changes in RPE cell size accompanied by an overall reduction in cell junction proteins in the $Opn4^{-/-}$ mutants. Our preliminary assessments suggest that the RPE changes preclude retinal degeneration. Accordingly, the degradation of phagosomes appears to be delayed suggesting that the rhythm of RPE phagocytosis is altered in the $Opn4^{-/-}$ animals. The diurnal exposure of phosphatidylserine is persistent suggesting that the early stages of phagocytosis are affected. The retinal and RPE pathologies are age-related and do not manifest in animals younger than eight months old.

Conclusions: Melanopsin signaling plays an important role during retinal development, however, the contribution of this signaling axis in retinal homeostasis is not well understood. Here we provide evidence that melanopsin signaling plays a critical role in protecting the aging retina from damage. Moreover, our data suggest that melanopsin signaling may play a critical role in the phagocytosis of the photoreceptor outer segment and raises the possibility that melanopsin could function in the RPE.

TITLE: Development of a Skin Biopsy-Based Calcification Assay for Detection of Optic Disc Drusen: A Pilot Study

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Imventarza, A. Kumar, Y.J. Liao, Ophthalmology, Stanford University, Palo Alto, California, UNITED STATES|J.A. Imventarza, A. Kumar, Y.J. Liao, Liao Eye-Brain Lab, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure: Joel Imventarza: Commercial Relationship: Code N (No Commercial Relationship) | Ajay Kumar: Commercial Relationship: Code N (No Commercial Relationship) | Yaping Liao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optic disc drusen are acellular calcified deposits in the anterior, unmyelinated optic nerve and occur in up to 2.4% of the population. The majority of patients develop vison loss due to optic neuropathy. These ectopic calcifications have been shown to consist of calcified mitochondria, which result from a combination of narrow scleral canal, impaired axoplasmic flow, and local metabolic stress, ischemia and inflammation. Both intra-and extracellular calcium concentrations are highly regulated by biological process, and mitochondria is known to be effective calcium buffering organelle intracellularly. We aimed to assess different conditions that promote calcification in human skin-derived primary human fibroblast cultures.

Methods: We cultured human fibroblasts and treated with different conditions for 21 days: 1-4 mM potassium phosphate, 2-6 mM tri-calcium phosphate, 2-3.2 mM sodium phosphate, 0.4-2 mM ibotenic acid, 1-10 mM 3-nitro-propionic acid, and osteogenic differentiation media (0.01 mM dexamethasone, 10 mM B-glycerophosphate, and 50 mM ascorbic acid). Calcification was evaluated by staining with Alizarin-red S and quantified by measuring optical density at 560nm using a plate reader. To assess cell viability, we performed MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay and absorbance measurement at 570 nm. We performed statistical analysis using one-way ANOVA and unpaired T test, and $p < 0.05$ was considered as statistically significant.

Results: Calcification in normal human fibroblast cultures, indicated by Alizarin-red S staining, was significantly induced by culturing for 21 days in elevated extracellular concentrations of calcium using potassium phosphate, tri-calcium phosphate, and sodium phosphate. This avid calcification did not impact cell viability per MTT assay. Excitotoxic toxins using ibotenic acid and 3-nitro-propionic acid did not induce calcification but did lead to lower cell viability. The highest level of calcification was induced with 4mM potassium phosphate (5.69±1) and 3.2 mM sodium phosphate (5.21±0.4).

Conclusions: Our study determined the optimal concentration of extracellular potassium and sodium phosphate that an induce calcification in primary human fibroblasts after 7 and 21 days in culture. This finding will help us design a novel in vitro assay for assessing increased risk of calcification in patients with optic disc drusen.

ABSTRACT BODY:

Purpose: We previously identified the neuropathological hallmarks of Alzheimer's Disease (AD), amyloid β-protein (Aβ) plaques and neurofibrillary tangles comprised of hyperphosphorylated tau (pTau) protein, in the retina of AD patients. Retinal Aβ deposits were detected in subjects with mild cognitive impairment (MCI) and AD, with variable distribution across cell layers and subregions. Loss of retinal ganglion cells (RGCs) was also documented in these patients. While increased pTau was also reported, there is still a gap in our understanding of retinal tauopathy in AD. Moreover, the topographical distribution of retinal pTau in AD and cell-type vulnerability has never been reported.

Methods: To quantify retinal pS396Tau in different subregions and cell layers and in RGCs, which express the ribonucleic acid binding protein with multiple splicing (RBPMS), we used quantitative immunohistochemical analyses. Manual count and immunoreactive-area of pTau-containing RGCs and RBPMS-positive RGCs were assessed in postmortem retinae of subjects with normal cognition (NC), MCI, or AD.

Results: We find a substantial 45% decrease in RBPMS-expressing RGCs in postmortem retinas of both MCI and AD patients. RBPMS cell loss was accompanied by 2-3-fold pS396Tau increases in prodromal and clinical AD retinae, especially in the superior-temporal mid-periphery region. While pS396Tau is densely observed in the outer plexiform layer (OPL), colocalization of pTau inside RBPMS-RGCs is also pronounced. Elevated pS396Tau in remaining RBPMS-RGCs may drive degeneration and displacement to deeper retinal layers in disease states.

Conclusions: The patterns of abnormal pS396Tau distribution in the human retina are described with increased vulnerability of RBPMS-expressing RGCs to pTau accumulation and loss. Future studies should investigate the susceptibility of other retinal cell types to tauopathy in early stages of AD.

ABSTRACT BODY:

Purpose: To analyse the incidence rates of ischaemic stroke among patients newly diagnosed with glaucoma at a regional ophthalmic institution in London, United Kingdom.

Methods: We conducted a retrospective cohort study of all patients >= 40 years of age and newly diagnosed with glaucoma between January 1st 2008 and March 31st 2018. Records were linked with national hospital admissions data and ischaemic stroke was defined through the International Classification of Diseases 10th Revision. Incidence rates with 95% confidence intervals were calculated using the Poisson distribution and adjusted hazard ratios (HR) through Cox proportional hazard modelling and Fine-Gray competing risks regression.

Results: Among 31,060 patients with a new diagnosis glaucoma, 16,322 (52.5%) were female, mean age was 64.8 (12.3) years and 512 had an ischaemic stroke with a crude incidence rate of 348.9 (319.5-380.0) per 100,00 person-years at risk. Glaucoma was diagnosed at a younger age in those of Asian (63.9 +/- 11.5) and Black (62.3 +/- 12.1) ethnicity versus those of White ethnicity (67.3 +/- 12.1, p<0.001); also in those at greater levels of socioeconomic deprivation (most deprived 62.5 +/- 12.3 years versus least deprived 66.3 +/- 11.9, p<0.001). On adjusted analysis, male sex (cause-specific HR 1.36, 1.14-1.62) and increasing age (1.08, 1.07-1.08) were associated with greater hazards of stroke; no significant association was seen with ethnicity or socioeconomic deprivation. Estimates from competing risks regression were similar to those from Cox modelling.

Conclusions: An earlier age of glaucoma diagnosis is seen in ethnic minority groups and those from greater levels of socioeconomic deprivation. Following glaucoma diagnosis, incidence of ischaemic stroke is higher in elderly males but does not appear to be associated with ethnicity or socioeconomic deprivation.

ABSTRACT BODY:

Purpose: 10% of patients invited to Moorfields Eye Hospital Oculoplastic video consultation (VC) clinics decline to participate, and 5% are unable to join on the day. 28% of our patients indicated that they would like to join sessions to improve their digital skills. Amidst growing evidence that some patient groups may be unable to capitalise on the benefits of teleophthalmology, we set up a digital skills workshop at Moorfields Eye Hospital.

Methods: Patients who had previously declined a VC - and those attending parallel clinics who were keen to improve their digital skills - were invited to participate. Delivered by a member of our Video Consultation Team using departmental laptops, tablets and patients' devices, training included using our VC platform, taking a 'selfie' photo of the eye, and sending it via email. Pre- and post-workshop surveys explored patients' confidence with online services, inclination to use VC and perceived utility of the workshop using a 10-point Likert scale (0 'extremely unlikely' to 10 'extremely likely'). Paired T-test was used to assess significance of difference between ratings before and after the workshop. Qualitative feedback was analysed thematically.

Results: Feedback was obtained from 16 patients of 24 patients (67% response rate). 58% were invited to the workshop after declining a VC; 42% attended ad hoc from a parallel clinic, interested in improving their digital skills. Average age was 63 years (69% male, 31% female). Patients reported greater inclination to use a VC after attending the workshop compared to before (mean rating 6.1/10 vs 4.75/10, p=0.02) and felt more comfortable with VCs after the workshop compared to before (mean rating 6.1/10 vs 4.5/10, p=0.005). Patients found the workshop useful (mean rating 7.8/10) and were likely to recommend it to family and friends (mean rating 8/10). The most common suggestion was for an interpreter for patients with limited command of English. Commonly reported barriers to using VCs were lack of: confidence navigating online (63%), awareness that health services could be accessed remotely (38%), and confidence that a VC would adequately address their health problem (38%).

Conclusions: Patients consider digital skills workshops useful to improve confidence and motivation with using online services. Scaling these workshops may help address an increasing issue of exclusion as services become more reliant on teleophthalmology.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is a major risk factor for the progression of primary open angle glaucoma (POAG). Damage to the trabecular meshwork (TM) is responsible for increased aqueous humor outflow resistance that raises IOP. Of the factors that are involved in TM dysfunction, mutation of the myocilin gene (MYOC) was the first identified. MYOC mutations contribute to ~4% of POAG cases. Although, the normal role of myocilin is unknown, mutations in MYOC cause a deleterious gain-of-function leading to lack of extracellular secretion and endoplasmic reticulum (ER) stress within TM cells. Our goal is to develop genome editing methods to modify genes associated with TM pathophysiology, which are not addressed by current IOP lowering therapies. We previously demonstrated the feasibility of targeting the mutant (mut)-MYOC gene using CRISPR/Cas9 genome editing in mice and human donor eyes using the adenovirus (Ad)-5 gene transfer system. However, Ad5 is not a suitable vector for clinical use. Therefore, we aim to study the efficacy of adeno-associated virus (AAV) and lenti virus (LV) vectors expressing CRISPR/Cas9 to target the TM and reverse ocular hypertension (OHT) in mut-MYOC associated POAG.

Methods: We compared the TM specific tropism of single-stranded (ss) and self-complimentary (sc) AAV serotypes with the LV vector that express eGFP driven by the CMV promoter. These vectors were injected via intravitreal (IVT) and intracameral (IC) routes to determine expression in ocular tissues. Efficient CRISPR-Cas9 constructs that selectively knockdown MYOC (cr-MYOC) were designed to evaluate the effect on ER stress markers in mut-MYOC expressing transformed TM cells and the effect on IOP in the transgenic (Tg)-MYOC^{Y437H} mouse model of OHT.

Results: Of the AAV serotype tested, Trp-mutant scAAV2 had prominent expression of eGFP in the TM via slow-IC route. However, expression was also observed in other retinal and optic nerve head tissues. In contrast, LV_eGFP expression was more specific to the TM injected via the IVT route. Cr-MYOC transduced cells were shown to have reduced expression of MYOC and ER stress markers GRP78, ATF4 and CHOP. LV_cr-MYOC injected mice show significantly reduced IOP in Tg-MYOC^{Y437H} mice.

Conclusions: LV was found to be more specific and efficient in mediating target gene expression in the TM and facilitate MYOC gene knockdown.

ABSTRACT BODY:

Purpose: A loading dose (LD) of three-monthly intravitreal injections of anti-vascular endothelial growth factor (anti-VEGF) is frequently used to determine treatment response. Here, we compare morphological and functional outcomes of bevacizumab on spectral domain-optical coherence tomography (SD-OCT) in eyes with center-involving diabetic macular edema (ciDME) pre- and post- LD.

Methods: IRB approved observational, retrospective chart review of treatment-naïve patients with ciDME who received bevacizumab injections from 01/01/2017 to 01/19/2019 who were identified by ICD-10 code. Exclusion criteria included previous treatment with anti-VEGF or intraocular steroids in the last year, poor quality images, or incomplete chart data/missing imaging. Variables tracked included best corrected visual acuity (BCVA) and central foveal thickness (CFT) before and after LD. Central foveal OCT frames were graded qualitatively using Imagivault software, including for disorganization of retinal inner layers (DRIL) and ellipsoid zone (EZ) disruption. Analysis of variance was conducted using SPSS.

Results: 330 potential subjects were identified, and after applying exclusion criteria 24 eyes from 21 patients (mean age 65.17 ± 7.86 years, 54.2% male) were analyzed. Mean BCVA was 0.31 ± 0.19 logMar (~20/40) at baseline and 0.33 ± 0.33 logMar (~20/40) after LD. Mean CFT decreased from 449 ± 105 µm at baseline to 405 ± 113 µm after LD. Using CFT reduction metrics, 5 (20.8%) of patients were categorized as responders (>20% reduction), 6 (25.0%) as partial responders (10-20% reduction), and 13 (54.2%) as non-responders (<10% reduction). Average change in CFT from baseline in responders was -213 µm; in partial responders -68 µm, and in non-responders +32 µm. DRIL was detected in 100% of responders, 83.3% of partial responders, and 100% of non-responders. EZ disruption was present in 0% of responders, 16.7% of partial responders and 30.8% of non-responders. At baseline, responders had a significantly increased mean CFT in comparison to non-responders ($p = 0.02$).

Conclusions: The response to a LD of bevacizumab in eyes with ciDME was sub-optimal with the majority of patients being non-responders. Factors indicative of a better response were increased baseline CFT and absence of EZ disruption.

SUBMITTER (NAME ONLY): Kevin Houston

TITLE: In Search of Pathological Suppression of Binocular Vision After Stroke: An Exploratory Study

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Houston, P. Tirandazi, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|K. Houston, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Kevin Houston: Commercial Relationship: Code N (No Commercial Relationship) | Pooyan Tirandazi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In a prior prospective study, 74% of stroke survivors with strabismus failed to report diplopia (Rowe, 2010). The possible reasons were investigated hypothesizing that pathological suppression exists and is related to laterally imbalanced attentional networks, and therefore associated with hemispatial neglect (HSN) and/or visual extinction (VE) after controlling for other reasonable factors.

Methods: A 1 year review of all inpatient vision clinic records included comprehensive eye and sensorimotor exam with 2AFC Randot E, Stereobook R+L and Randot Stereopsis, TV trainer, induced strabismus test, covertest, motorfield, motility and NPC. Evaluation for HSN included line bisection, cancellation, and VE. Failed suppression tests were tabulated and the clinician reviewer, considering all information, rated(1-10) the likelihood-certainty of suppression vs. another explanation. Hypothesized association of HSN and VE with likelihood rating and proportion of test failures was analyzed.

Results: There were 113 consecutive records with ≥1 suppression test (median 4, range 1-10). Only 33% passed all suppression tests administered. 47% did not have diplopia with optically induced strabismus. Actual strabismus was present in 50%, of whom 49% denied diplopia. Randot stereopsis was failed in 64%, and stereobook R+L in 23%. Potential confounders reported as most limiting clinician reviewer certainty were homonymous hemianopia (HH), order effects with preceding tests potentially breaking suppression, and generalized reduction of awareness/insight. Multiple regression analysis did not support HH or interocular acuity differences as confounders. Insight and order effects could not be tested. HSN was a significant predictor of suppression certainty P=.001, controlling for age P=.004. Post hoc exploration of other possible factors via forward selection identified VE P<.001 and subsequently parietal lobe involvement P=0.03 as independent predictors, with age, HSN, and VE ultimately dropping out.

Conclusions: Findings support the hypothesis that failure to report diplopia from strabismus after stroke is common and that there is relationship to HSN, or more specifically VE and the associated parietal corticies. Prospective studies would allow for control of potentially confounding order effects and generally reduced insight for impairment in stroke patients, while introducing psychophysical and dichoptic testing paradigms.

ABSTRACT BODY:

Purpose: Anti-VEGF injections are often used for the treatment of macular edema from retinal vein occlusions (RVO). Variable response to intravitreal bevacizumab has been reported for treatment of diabetic macular edema (DME). In this study, we performed a retrospective chart review to examine potential racial variances in treatment response to bevacizumab in patients with macular edema secondary to RVO.

Methods: Intravitreal anti-VEGF naïve patients aged over 18 who received at least one intravitreal bevacizumab injection for central and branch RVO were included. Data were collected before treatment, 1-3 months after the first injection, and 1-3 months after 3 injections. Primary outcome measures were percentage of patients with visual acuity (VA) improvement (defined as >0.1 on logMAR scale), reduction in central macular thickness (CMT), and the presence of systemic disease. Analysis was performed using multivariate regression for percentage change of CMT and logistic regression for percentage of patients with VA improvement.

Results: 156 eyes were included for the single injection analysis and 101 for the 3-injection analysis. There was no significant difference in odds of VA improvement between Black (B) and White (W) patients after one injection (B=51.9%, W=55.7%, OR 1.20, P=0.66) and after 3 injections (B=70.4%, W=68.1%, OR 1.48, P=0.55) after controlling for age, sex, baseline VA, baseline CMT, laser history, injection time course, follow-up delay, and presence of hypertension, diabetes, and hyperlipidemia. Similarly, there were no differences in %CMT reduction among the race groups after one injection (B= -30.8%, W= -27.5%, p=0.78) and after 3 injections (B= -25.8%, W= -32.8%, p=0.52) using the same controls. Among all patients, there were higher rates of hypertension in Black compared to White patients (66% vs 46%, p= 0.02). Rates of diabetes appeared higher in Black compared to White patients but were not statistically significant (B=25%, W=12%, p=0.06).

Conclusions: There were no statistically significant differences in treatment response to a single or a series of 3 bevacizumab injections in patients with macular edema secondary to RVO across different races despite a significant difference in presence of hypertension. These results are in contrast to a prior study done by our group with similar methodology for DME.

ABSTRACT BODY:
Purpose: There is limited evidence describing the effects of amblyopia treatment in eyes with coexisting optic nerve pathology (ONP). The purpose of the study was to evaluate the visual acuity outcomes following patching treatment of eyes with coexisting ONP.
Methods: Retrospective cohort study undertaken at a single university outpatient clinic setting. Clinical records of pediatric patients with a diagnosis of amblyopia coexisting with ONP were reviewed. Baseline presenting visual acuity (B-VA) and final best corrected visual acuity (F-VA) were recorded using Snellen eye charts and converted to their corresponding logMAR values. Primary outcome was the F-VA attained with ≥1 year patching and refractive correction. Secondary outcome was the prevalence of eyes with F-VA ≥20/40. F-VA was categorized into four groups. Difference between F-VA and B-VA was calculated for each eye (Diff-VA). Wilcoxon signed rank sum test was conducted to evaluate Diff-VA for all subjects that had B-VA and F-VA as measured with Snellen chart. Spearman correlation analysis was conducted to analyze the association between B-VA and F-VA.
Results:
The clinical records of 7 eyes of seven patients with a mean baseline age of 6.8±2.6 years (range: 4-10 years) who had ONP, had patching treatment and had Snellen VA tests recorded were included in this study. Optic nerve hypoplasia, optic nerve atrophy, myelinated nerve fibers, and traumatic optic neuropathy were the various etiologies of ONP included. The mean B-VA and F-VA in logMAR were calculated as 0.976±0.509 and 0.723±0.188, respectively. A final Snellen VA of <20/200 was attained in 0%, 20/200–20/60 in 85.7%, and 20/60–20/40 in 14.3% of the eyes. None of the eyes that received amblyopia treatment achieved a F-VA≥ 20/40. The mean Diff-VA for the 7 eyes that had visual acuity measurements available for analysis was -0.252 ± 0.377 (p=0.156). F-VA was not found to be associated with B-VA (rho=0.593; p=0.161).
Conclusions: Our results suggest that regardless of the underlying pathology, final visual function in amblyopic eyes with coexisting ONP remains between 20/200 and 20/40. Baseline visual function does not appear to be predictive of final visual outcomes in these eyes. Although patching treatment may result in modest increase in visual function, childhood onset ONP appears to confer a poor prognosis for visual function.

ABSTRACT BODY:

Purpose: To perform clinical validation of RETINA-AI Galaxy, a Multi-Camera Compatible Autonomous Artificial Intelligence System for Diabetic Retinopathy Screening in Primary Care

Methods: The study involved 4 U.S. primary care sites from where subjects were recruited. 397 study subjects ages 22 and above who had diabetes and had not been previously diagnosed with more than mild diabetic retinopathy were prospectively enrolled between March 25, 2021 and May 28, 2021. ClinicalTrials.gov ID: NCT04774822. Subjects underwent an AI screening protocol in which one fovea-centered and one optic disc-centered image were taken for each eye for each of the 5 robotic fundus cameras in the study. The images were then transmitted to the cloud-based software-as-a-medical AI device for analysis. 4W-D validation stereoscopic fundus imaging along with optical coherence tomography (OCT) macula cube scanning was also done. Validation imaging was interpreted by three American Board of Ophthalmology-certified retina specialists. Primary endpoints were sensitivity and specificity of detection of more than mild diabetic retinopathy (mtmDR) detection and vision-threatening diabetic retinopathy (vtDR), using double grading with adjudcation on a probabilistic grading schema filter, Certainty Ratio >3/5:=mtmDR. 95% CI shown in Figures was via clustered bootstrap.

Results: On the DRSPlus, Crystalvue, Topcon, DRS, and Nexy cameras respectively: for mtmDR detection, Area Under the ROC curve (AUC) was 0.97, 0.93, 0.95, 0.95, and 0.91 respectively; and (Sensitivity, Specificity near 82.5%) were (94.97%, 82.6%), (89.24%, 82.5%), (87.34%, 83.2%), (88.24%, 85.3%), and (83.65%, 82.6%) respectively. For vtDR, AUCs were 0.97, 0.91, 0.96, 0.97, and 0.93 respectively; and (Sensitivity, Specificity near 82.5%) were (97.06%, 84%), (88.24%, 88.1%), (93.94%, 94.8%), (94.12%, 85%), and (94.12%, 90.9%) respectively. On the Blinded Assessment, (Sensitivity, Specificity) of mtmDR were (90.6%, 90.6%), (87.3%, 84.7%), (81.6%, 93.2%), (83%, 92.8%), and (78.6%, 87%) respectively; and for vtDR were (73.5%, 96.2%), (82.4%, 91.3%), (93.9%, 94.5%), (91.2%, 94%), (91.2%, 92.4%) respectively.

Conclusions: The multi-camera compatible AI system met primary endpoints, demonstrating efficacy and safety in the detection of more than mild diabetic retinopathy and vision threatening diabetic retinopathy in the primary care setting.

ABSTRACT BODY:

Purpose: Functional Magnetic Resonance Imaging (fMRI) measures neural activity indirectly by monitoring local changes in blood oxygenation and blood flow. Altered patterns of cerebral blood flow that occur, for instance, in stroke patients, may affect the analysis and interpretation of fMRI data. Here we investigate relations between experimental design and altered hemodynamic responses using computational approaches modeled on the early visual system.

Methods: Population receptive field mapping is used to localize cortical representation of different regions of the visual field. We used computational modeling to determine how the accuracy and precision of population receptive field mapping is affected by altered hemodynamic responses in two conditions: 1) stimuli presented sweeping across the visual field and 2) stimuli presented randomly across the visual field. Hemodynamic response functions for both analyses were modeled using a 2-gamma function with a time-to-peak varying between 0 and 12 repetition times (TRs) from stimulus onset.

Results: We found that the analysis was more robust to an altered hemodynamic response when the stimuli were presented in a random sequence. Sequential stimulus presentation led to systematic errors, that were not present with the random presentation sequence, leading to an increase in Type I errors (false positive). For both stimulus presentation methods, the sensitivity and specificity of the analysis greatly deteriorated if the time-to-peak was delayed by greater than +/- 1 TR.

Conclusions: These results highlight the importance of tailoring the experimental design to altered hemodynamic responses and point to the need for subject- and voxel-specific hemodynamic response functions when analyzing fMRI data in patient populations with neurovascular abnormalities. Without these modifications, researchers run the risk of making incorrect conclusions about retinotopic reorganization.

TITLE: Improving ultrafast ophthalmic adaptive optics by accounting for deformable mirror actuation

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Liu, J. Crowell, M. Bernucci, D.T. Miller, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|K. Kurokawa, Legacy Devers Eye Institute at Legacy Good Samaritan Medical Center, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Yan Liu: Commercial Relationship: Code N (No Commercial Relationship) | James Crowell: Commercial Relationship: Code N (No Commercial Relationship) | Kazuhiro Kurokawa: Commercial Relationship(s);Code P (Patent):Indiana University Bloomington | Marcel Bernucci: Commercial Relationship: Code N (No Commercial Relationship) | Donald Miller: Commercial Relationship(s);Code P (Patent):Indiana University Bloomington

ABSTRACT BODY:

Purpose: Ultrafast ophthalmic adaptive optics (AO) outperforms conventional AO in correcting ocular aberrations and improves AO clinical utility [1]. However, the higher loop rate necessitates shorter wavefront sensor exposure durations that are comparable with deformable mirror (DM) response time. Thus, DM actuation may corrupt the sensor measurement and degrade the AO performance. Here, we study this effect and develop a way to minimize it.

Methods: Our AO system [1] consists of (1) a Shack-Hartmann wavefront sensor (SHWS) with 300 lenslets that sample a 6.7 mm eye pupil and a rolling-shutter camera (0.1 ms exposure time) that captures the SHWS images, and (2) a DM (ALPAO high-speed DM97-15) with a 1 ms rise time followed by ringing as specified by the manufacturer. To study the DM actuation effect, we controlled the delay between sending control commands to the DM and start of the SHWS exposure. We compared the power rejection curves (for pink noise applied to the DM) and step responses to fixed aberrations for exposure delays of 0, 1 and 6 ms. 0-ms delay exposes the SHWS to almost the entire DM response and 6-ms delay avoids it entirely. The rows of lenslets affected by DM actuation were determined by comparing the lenslet spot displacements, from which we determined the optimal delay.

Results: Overshoot of the step response to a large aberration (2.7 μm RMS wavefront error) occurred for the 0-ms exposure delay, while no overshoot occurred for the 1- and 6-ms delays. DM actuation affected the top two rows of SHWS lenslets (out of 20) for the 0-ms exposure delay and no rows for the 1-ms delay. Because the rolling shutter exposes rows from top to bottom in 3 ms, 0.3 ms was therefore determined as the optimal exposure delay. Reducing exposure delay from 1 ms to 0.3 ms, AO loop rate increased 17% to 233 Hz; closed-loop bandwidth increased 14% to 37.2 Hz; convergence time to diffraction limit reduced 14% to 4.3 ms; and power rejection curve peak magnitude remained the same. For smaller aberrations (0.32 μm RMS wavefront error, comparable to ocular aberrations after spectacle correction), no overshoot was observed in the step response for 0-ms delay, and closed-loop bandwidth increased 21% to 39.3 Hz compared with 1-ms delay.

Conclusions: DM actuation reduces AO performance when aberrations are large, but this decrease can be greatly reduced with the right exposure delay.

ABSTRACT BODY:

Purpose: The main function of vitamin D3 in the human body is to participate in the metabolism of calcium and phosphate, but, as it is actually a hormone, it also has an important immunomodulating action, presenting important biological activity in the innate and adaptive immune system, and acting in practically all tissues, since various types of cells have receptors and activating enzymes, including in the eye. Studies have shown that serum vitamin D3 deficiency is related to several eye diseases, such as dry eye, uveitis, AMD, glaucoma, diabetic retinopathy, and keratoconus, but very little is said about the relationship between tear levels of this vitamin and eye diseases; In this work, we will study the relationship between tear and serum levels of vitamin D3 in cases of keratoconus and in control cases.

Methods: This study was performed with 71 individuals, being 32 individuals with keratoconus in both eyes (64 eyes),15 men and 17 women, aged between 16 to 27 years (mean 20,5 years), and 39 individuals without eye disease (control group with 78 eyes), 12 men and 27 women, aged between 19 to 27 years old (mean 21,75 years). Serum and tear vitamin D3 were evaluated in all participants.Tears were collected using the Schirmer strip in the all eyes with keratoconus and in the all eyes of the control group; for serum examination, 3 milliliters of venous blood were collected from all participants in this study. All blood and tear samples had their vitamin D3 levels assessed, by their metabolite 25 (OH) vitamin D3, by electrochemiluminescence examination, and statistical analysis was performed by the Chi-square test.

Results: In the group of individuals with keratoconus, the average verified level of vitamin D in the tear was 73.03 ng /ml, ranging from 57.5 to 88.4 ng / ml, whereas in all tear samples in the control group, the levels were above 100 ng /ml, the upper limit of detection of the electrochemiluminescence apparatus, with $p < 0.0001$. In blood samples, the mean found in the group of individuals with keratoconus was 21.36 ng / ml, while in the control group it was 29.95 ng /ml, with $p < 0.05$.

Conclusions: Compared with control eyes, the results of vitamin D3 levels were significantly lower both in plasma and in tears, particularly in tears, thereby demonstrating the important relationship of vitamin D3 levels in keratoconus; these results allow us to suggest that tear vitamin D3 level could be a potential biomarker for keratoconus

ABSTRACT BODY:

Purpose: Alzheimer’s disease (AD) is a complex multifactorial disease that affects 33 to 38 million people worldwide, causing irreversible damage to the central nervous system. In the eye, the retinal phenotype is consistent with the brain histopathology, including the presence of beta-amyloid (Aß) plaques and intracellular neurofibrillary tangles (NFT) of abnormally phosphorylated Tau proteins (pTau). Unfortunately, no treatment exists to cure this disease. Thus, we set out to develop and characterize the first hiPSC-derived organoid model of retinal AD histopathology that can be used for the validation of potential therapeutic drugs.

Methods: hiPSC from 3 wild type (WT) and 2 familial AD (fAD) donors were used to generate retinal organoids (RO) using the Zhong et al. (2014) protocol. The cellular composition and histopathological hallmarks of AD were assessed at 6 months of differentiation by Western blot, immunofluorescence staining for retinal cell type-markers as well as Aβ and pathological pTau forms, and by NIAD-4 staining for amyloid plaques. Quantification was performed using FIJI software for 2D images and 3D-ARQ for whole mount ROs.

Results: AD-ROs are similar to WT-ROs in cellular composition and structure. However, pathological pTau staining and Aß deposits are significantly increased in AD-ROs compared to WT-ROs. Finally, we developed a quantitative, high-throughput assay for plaque detection that is amenable to translational research applications.

Conclusions: Our AD-RO models mimic the histopathology of the human AD retina and constitute valuable tools for the screening and validation of candidate molecules with therapeutic potential.

TITLE: Latent Transforming Growth Factor-β Binding Protein 1 expression in the corneal stroma

SESSION TITLE: Corneal stromal biology, wound healing modulators, and regeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E.M. Espana, S. Salvatori, M. Sun, D. Cogswell, USF Health Morsani College of Medicine, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure: Edgar Espana: Commercial Relationship(s);Code C (Consultant/Contractor):GSK | Sarah Salvatori: Commercial Relationship: Code N (No Commercial Relationship) | Mei Sun: Commercial Relationship: Code N (No Commercial Relationship) | Devon Cogswell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Latent Transforming Growth Factor-β Binding Protein 1 (LTBP1) is poorly characterized in the cornea, and our knowledge of its function is mostly unknown. The aim of the current study was to elucidate the expression and role(s) of LTBP1 in regulating corneal stromal structure and function during homeostasis and following injury. The biological importance of LTBP1 radicates in its property to maintain Transforming Growth Factor (TGF) - β latent.

Methods: Analysis of LTBP1 expression, temporal and spatial, was performed at different postnatal days (P) in wild-type C57BL/6 mouse corneal stromas and after injury. Ltbp1 mRNA expression as well as LTBP1 protein content and locatization with stromal maturation were studied. Total (latent + active) TGF- β was analyzed in vitro using transformed mink lung cells transfected with luciferase cDNA driven by PAI-1 promoter. To test the amount of total TGF-β stored in the stromal matrix at different ages, we measured exactly similar aliquots of stromal extract at different ages.

Results: Ltbp1 mRNA stromal expression, obtained after enymatic removal of corneal epithelium, was present at P4 but decreased with corneal maturation at P10, P30 and P140. There was a signficant decrease in Ltbp1 mRNA expression with corneal maturation. In contrast, Wes protein analysis showed increased deposition of LTBP1 with corneal maturation. Highest levels were noted at P140, the oldest age in which protein expression was investigated. Immunofluorescent microscopy showed LTBP1expresion in all ages studied with expression of LTBP1 localized to the extracellular matrix in the entire stromal thickness. Ltbp1 mRNA was significantly upregulated after injury and LTBP1 expression up-regulated following two different injury models: stromal abrasion and full thickness laceration. Besides, we investigated whether increased LTBP1 expression with corneal maturation correlated with increased TGF- β activity since it is well established that LTBP1 is the main regulator of latent TGF- β. We found a statistically significant increase in total TGF- β stromal corneal with corneal maturation, P30 vs P150, t-test, unpaired, p=0.04.

Conclusions: This study indicates that LTBP1 plays a regulatory role in corneal development and in the function of the adult cornea. LTBP1 deposition and total TGF-β storage increase during stromal maturtion. The expression of LTBP1 is recapitulated during wound healing.

ABSTRACT BODY:

Purpose: To evaluate the long-term surgical outcomes of tube shunt (TS) surgery in patients with various types of glaucoma.

Methods: This retrospective chart review included patients who underwent TS surgery from 01/2006 to 01/ 2012. Patients with at least 10-years of follow-up data were included. Demographic and clinical data were collected at the pre-operative and post-operative follow-up visits until their latest visit (up to 01/2022). Surgical failures were defined as eyes that required reoperation or progressed to no light perception (NLP).

Results: 30 eyes of 26 patients were included. Mean age was 60.4±10.2 with a mean follow-up of 12.1±1.8 years after their first TS surgery. At the last visit, BCVA in the operated eye declined from 0.9±0.8 to 1.4±0.9 ($p=0.006$), CDR increased from 0.6±0.2 to 0.8±0.2 ($p=0.01$), VF progressed from -11.7±7.4 to -16.4±7.1 ($p=0.53$), IOP lowered from 31.0±11.0 mmHg to 12.5±11.9 mmHg ($p<0.01$) but lowered to 12.6 ±14.5 mmHg among patients with no reoperation ($p<0.01$), and glaucoma medication use reduced from 3.1±1.2 to 2.1±1.6 regardless of need for reoperation ($p=0.013$). 18 eyes (60%) had vision worse than 20/200 at their last visit and 2 eyes (6.7%) progressing to NLP. 6 eyes (20%) required additional TS surgery within 10-years with a mean IOP of 27.6±15.4 before the subsequent TS surgery. Among the 16 eyes with an Ahmed valve, 6 eyes (37.5%) required additional surgical intervention: 3 eyes underwent cyclophotocoagulations (CPC) (18.7%), 1 trabeculectomy (Trab) (6.2%), and 2 needed a second TS (12.5%). Among the 13 eyes with a Baerveldt implant, 4 eyes (31.2%) required additional surgery, 2 (15.6%) of which required two procedures. 1 eye required a new TS, 1 needed a Trab, 1 eye underwent Trab + CPC (7.8%), and 1 eye needed both a TS (switched to Ahmed valve) + CPC (7.8% each). During the follow-up period, 7 eyes (23.3%), 4 eyes (13.3%), and 3 eyes (10%) required one, two, and three TS revisions, respectively.

Conclusions: In this long-term retrospective study, patients undergoing TS surgery overall had maintained a therapeutic IOP and useful vision. However, a significant portion of patients underwent additional procedures with approximately a third of eyes requiring additional surgical interventions.

ABSTRACT BODY:

Purpose: The cone-dominant 13 lined ground squirrel (13-LGS) is an emerging model for vision research. Here, we sought to characterize a naturally occurring hypopigmented 13-LGS model using non-invasive imaging.

Methods: Six (5M, 1F) 13-LGS from the same hypopigmented pedigree were anesthetized and underwent non-invasive retinal imaging and axial length measurement. Near infrared reflectance (NIR), Near infrared autofluorescence (NI-AF), and short wavelength autofluorescence (SW-AF) scanning laser ophthalmoscopy (SLO) imaging was used for qualitative assessment. Optical coherence tomography (OCT) scans were obtained to quantify retinal thickness. Adaptive optics scanning light ophthalmoscope (AOSLO) images were acquired along vertical strips from the optic nerve head (ONH) inferior to the visual streak. Regions of interest were then selected at 0.75° increments along this strip to estimate cone density. Quantitative metrics were compared to eccentricity matched data from one-year-old wildtype animals (OCT: n = 12 eyes, AOSLO: n = 6 eyes).

Results: SLO imaging revealed variable choroidal visualization in all animals. Two animals had substantially shorter axial length values (5.87 and 5.90 mm; normal range = 8.53 - 8.9 mm). These two animals had significantly increased total retina, inner retina, outer retina, and choroidal thicknesses, while thickness values for the other 4 animals were within normative ranges (see Figure). AOSLO imaging was not possible in the two short-eyed animals due to poor image quality. In remaining hypopigmented animals, density measurements fell within ± 2 SD of the normative eccentricity matched mean values (c.f., at 6.25 degrees eccentricity, normal mean ± 2SD: 534.98 ± 115.46 cones/deg^2; hypopigmented range: 522.37 – 594.09 cones/deg^2).

Conclusions: While some of the hypopigmented 13-LGS present similarly to wildtype animals, the decreased axial length, abnormal OCT, and altered SLO observed in two of the hypopigmented animals present similarly to that of human albinism patients. This supports continued examination of the hypopigmented 13-LGS pedigree as an emerging model to study human albinism.

ABSTRACT BODY:

Purpose: A comparative clinical trial was conducted to evaluate the effectiveness of a virtual bioptic telescope in an HMD vision enhancement system possessing a wide field of view to currently employed specifications in HMD vision enhancement technology through patient reported outcome measures. As HMDs are being developed and implemented into clinical vision rehabilitation, it is important to evaluate the effectiveness of new features as it translates into the functional ability of visually impaired individuals.

Methods: Patients were randomized into two arms with the following HMD specifications: 1. a magnification bubble embedded in an unmagnified 70° field of view (bubble) and 2. full-screen magnification in a 45° field of view (legacy). Participants completed baseline testing then took the device home for a 2-4 week trial period. Participants were encouraged to use the device in their daily activities (excluding mobility). The Activity Inventory (AI) was administered before and after the home trial to measure the effect of system use on self-reported functional ability measures. Baseline and follow-up AI results were analyzed using Rasch analysis.

Results: A total of 88 (n=44 legacy, n=44 bubble) participants with BCVA of <20/60 in the better-seeing eye and at least 70° of peripheral visual field completed the study. There was no difference in age, BCVA, or baseline AI person measures between groups. In the legacy group, improvements were seen in reading (Cohen's d=0.99, p <0.001) and inside-the-home tasks (d=0.44, p=0.04). In the bubble group, improvements were seen in reading (d=0.82, p <0.001) and visual information tasks (d=0.39, p=0.03). There was no improvement in visual motor function or mobility in either group. Between group effects did not reach statistical significance.

Conclusions: Based on the AI results, use of both the legacy and bubble HMD result in improvements in reading, visual information (i.e. seeing faces), and inside-the-home tasks with reading having the strongest effect size. The lack of improvement in mobility and visual motor function is expected and likely due to limited field of view and lack of binocular disparity. There were trends for legacy device users to report better outcomes with reading and in-home tasks and bubble users to report better outcomes with visual information tasks, but there was no significant difference between groups.

TITLE: Utility of the red reflex test for detecting posterior ophthalmic pathology in the pediatric population

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Dortonne, M. Manrique, S. Rana, W. Madigan, Ophthalmology, Children's National Hospital, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure: Isabelle Dortonne: Commercial Relationship: Code N (No Commercial Relationship) | Monica Manrique: Commercial Relationship: Code N (No Commercial Relationship) | Sohel Rana: Commercial Relationship: Code N (No Commercial Relationship) | William Madigan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The red reflex test (RRT) continues to be an important part of the ophthalmology screening exam in the pediatric population to ensure early detection of ocular pathologies. Although RRT is considered a reliable examination technique for identifying anterior segment pathology (ASP), significant limitations in accurately detecting posterior segment pathology (PSP) have been reported. Delayed diagnosis of such conditions in children may cause permanent visual impairment leading to morbidity. This study aims to evaluate the utility of RRT for detecting ASP and PSP in the pediatric population. Furthermore, we aim to evaluate the impact of pharmacologic dilation and room illumination on the sensitivity and specificity of RRT.

Methods: After IRB approval, a prospective gathering of data was conducted at our tertiary care institution. Ophthalmology residents/fellows blinded to the patient's ophthalmologic diagnosis, performed a standardized RRT both in a dark room and a room with standard illumination. The RRT was repeated in the same manner after pharmacological pupil dilation. Finally, the patient was examined by a retina specialist to identify any ocular pathology. Analysis was performed using R statistical software.

Results: 34 eyes were analyzed. Mean age was 7.7 ±4.8 years. The RRT showed higher sensitivity and negative predictive value (NPV) for ASP; however, specificity rates and positive predictive value (PPV) were higher for PSP (table 1). There was no significant difference between RRT results in ambient light versus a dark room for both ASP and PSP. Dilation did not produce a statistically significant difference in RRT results (table 2).

Conclusions: Red reflex testing is an economical, effective screening method for children that provides a high sensitivity and negative predictive value for ASP such as cataract and corneal abnormalities. For any symptoms concerning for PSP, patients should be referred for prompt evaluation by an ophthalmologist regardless of their RRT findings. This study also finds that it is appropriate to conduct RRT in both ambient and dark lighting conditions. Furthermore, pediatricians can adequately conduct RRT without the need for dilation drops, which may improve times of consultation during a young child’s visit.

ABSTRACT BODY:

Purpose: To test a hypothesis that Periaxin (Prx) gene variant of 129 mouse strain background acts as a gain-of-function variant to facilitate severe nuclear cataract in connexin 46 knockout (Cx46KO) lenses by characterizing Prx-Cx46 double knockout (DKO) lens phenotypes. To determine the underlying cellular mechanism for functional association between connexin 46 and periaxin in lens homeostasis, stiffness and cataract formation.

Methods: Biochemical approaches including western blotting and morphological tools including laser confocal microscopic imaging were used to characterize and compare the molecular and cellular changes among lenses of wild-type, Cx46KO at different strain backgrounds and the Prx-Cx46 DKO mice in vivo. Prx gene variances were characterized in cultured cells in vitro.

Results: Severe nuclear cataracts in Cx46KO lenses were associated with the presence of highly expressed 129-periaxin proteins that were colocalized with F-actin in protrusions in lens fiber cells. The presence of 129-periaxin appeared to be associated with increased lens stiffness. Prx-Cx46 DKO at 129 strain background developed mild cataract that was similar to mild cataract in Cx46KO at C57BL/6J background, which expressed a low level of Prx variant in lens fibers.

Conclusions: Mild cataracts in DKO lenses suggest that a loss of periaxin significantly attenuate the development of severe nuclear cataracts in Cx46KO lenses at 129 strain background and 129-Prx gene acts as a gain-of-function variant to facilitate cataractogenesis caused by increased calcium levels in Cx46KO lenses. This result further indicates that both Cx46-mediated cell communication and Prx-mediated membrane-cytoskeletal complex regulate the calcium homeostasis in the lens fibers.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) stage is classified based on the appearance of the ridge on ophthalmoscopy or imaging. Using ultra-widefield (UWF) optical coherence tomography (OCT) we hypothesized that we could measure the axial thickness of the peripheral ridge, and that there is a positive correlation between stage category and ridge thickness.

Methods: We captured 26 unique ridge portions (showing at least 3 continuous clock hours of disease) in 11 patients with stage 1 to 3 ROP using portable, swept-source OCT with up to a 140° field of view (FOV). Area from the retinal pigment epithelium to the inner ridge surface was manually segmented (Figure 1), and axial thickness was calculated pixel-wise (1 pixel=4.4 μm) along the transverse dimension. A masked grader provided diagnosis of max stage using International Classification of ROP (ICROP) guidelines, as well as a second label representing a continuous spectrum of stage (e.g. 1.5). We compared ridge thickness (mean and standard deviation [SD]) to stage categories (analysis of variance [ANOVA]) and the stage spectrum (linear regression).

Results: The mean (+SD) ridge thickness increased with stage classification, with thickness of 252 (+49), 340 (+77), and 380 (+95) μm for stages 1, 2, and 3, respectively ($p=0.04$ by ANOVA). There was a significant relationship between the max ridge thickness and the continuous stage labels (Figure 2, $R^2=0.566$; $p<0.001$).

Conclusions: UWF OCT measurement of retinal thickness at the peripheral ridge correlated with ICROP stage classification and with continuous approximation of stage labels. These results suggest that OCT may provide objective and quantifiable biomarkers for ROP stage in the future, and that ROP severity overall may be better represented as a spectrum, since it varies both axially and circumferentially in eyes with ROP.

TITLE: Both Street Width and Direction of Traffic Flow Contribute to Making Streets Difficult to Cross for Pedestrians

SESSION TITLE: Mobility, Reading and Driving with Vision Impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.E. Hassan, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Shirin Hassan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: My lab has previously shown that young and older pedestrians alike find a two-way street more difficult to cross than either a one lane, one-way street or a roundabout. However, what makes the two-way street more difficult to cross? Is it the greater street width and/or the opposing directions of traffic flow? This study aimed to determine the individual effects of street width and traffic direction on the safety of crossing decisions.

Methods: 30 young, 13 young-old and 19 older-old subjects with normal vision made crossing decisions about whether or not they thought it was safe to cross at three different types of streets; a one lane, one-way street (one-way), a two-way street and a street that had two lanes of one-way traffic. Crossing decisions at each street type were made for a range of vehicular gap times. The percentage of unsafe decisions was calculated for each subject at each street by computing the number of times a subject deemed it was safe to cross when the measured gap time at a particular street was shorter than the subject's measured crossing time at that street. A linear mixed model with repeated measures for subject was used to determine if the percentage of unsafe decisions changed as a function of age and type of street.

Results: We found that all age groups made significantly more unsafe decisions at the wider street of two lanes of one-way traffic compared to the one-way street ($p<0.0001$). When assessing the effect of traffic direction, performance varied as a function of age. Specifically, young subjects made significantly more unsafe decisions at the two-way street compared to the two lanes of one-way traffic ($p<0.0001$). While the young-old subjects made a similar number of unsafe decisions at the two lanes of one-way compared to the two-way street ($p=0.41$), the older-old subjects made significantly more unsafe decisions at the two lanes of one-way traffic compared to the two-way street ($p<0.0001$). All subjects, irrespective of age, made significantly more unsafe decisions at the two-way street compared to the one-way street ($p<0.0001$).

Conclusions: Our data suggests that street width and the direction of traffic flow both increase the level of difficulty of making a safe crossing decision. It appears that with increasing age, pedestrians have more difficulty simultaneously processing information from two lanes compared to just one lane at a time.

ABSTRACT BODY:

Purpose: Severe hypotony following successful complex retinal detachment (RD) repair can progress to phthisis bulbi without intervention, even in the setting of long-term postoperative intraocular tamponade with silicone oil. It is also known that the use of periocular and intraocular steroids has been seen to induce an elevated intraocular pressure (IOP) response in some eyes. This study sought to assess the impact of topical difluprednate on raising intraocular pressure in patients with hypotony following surgical repair of a complex-RD.

Methods: A retrospective, consecutive case series was conducted on patients treated with difluprednate after successful complex RD repair at Associated Retinal Consultants (ARC, Royal Oak, Michigan) from January 2013 to June 2021. Patients were identified as having had complex RD repair by Current Procedural Terminology (CPT) code.

Results: Medical records of 230 patients were reviewed and 39 eyes of 39 patients were found to develop hypotony (IOP < 8 mmHg), despite having complete retinal reattachment and not having cyclitic membranes, at least 1 month after their last surgery. The majority of patients were left with long term silicone oil tamponade (26 of 39, 66.6%) and had required a retinectomy at the time of surgical repair (30 of 39, 76.9%). Patients presented with hypotony an average of 41 days after their last surgery (6-167 days). After initiation of topical difluprednate, there was a statistically significant increase in mean IOP (5.6mmHg) and at the patient's final follow up (8.6 mmHg, p=0.032).The average follow-up was 833 days after difluprednate initiation (range 76-2406 days). One patients progressed to phthisis bulbi, and all remained with complete retinal attachment at the last follow-up visit.

Conclusions: Topical difluprednate therapy for hypotony following successful complex RD repair resulted in a statistically significant increase in IOP and prevented phthisis bulbi in a majority of patients.

ABSTRACT BODY:

Purpose: Early detection of diabetic retinopathy (DR) is vital in preventing poor visual outcomes and is done with ultra-widefield color fundus photos (CFP) and fluorescein angiography (FA). Optical coherence tomography angiography (OCTA) may have a role but limited literature exists. Here we aim to determine the potential utility of OCTA in DR screening.

Methods: This is an IRB-approved retrospective image analysis of subjects with type 1 or 2 diabetes mellitus with or without DR at a single academic center. Subjects received FA and CFP (OPTOS, UK) and OCTA (Plex-Elite, Zeiss, Germany) in the same eye, same day. The arteriovenous and late phase frames were used for FA and 12x12mm vitreo-retinal interface (VRI) and superficial plexus slabs for OCTA. Images were analyzed by three masked graders on Imagivault (Melbourne, Australia). Graders evaluated for enlarged/irregular foveal avascular zone (FAZ), venous beading (VB), intraretinal microvascular abnormalities (IRMA), microaneurysms (MA), nonperfusion (NP), and neovascularization elsewhere (NVE) or disc (NVD). Images with poor quality or artifacts were excluded. We estimated sensitivities and specificities of features against FA as gold standard and Fleiss Kappa for intergrader agreement and reliability.

Results: From 43 total eyes, 36 met inclusion criteria. Mean age was 57 with 14 mild, moderate, or severe NPDR, 19 PDR, and 3 no DR. OCTA sensitivity was 0.94-1.00 for all features and specificity 0.75-1.00 in detection of MA, IRMA, NVE, NVD, NPA, and VB. CFP had sensitivity in detecting VB, MA, NVE, and NVD from 0.89 to 1.00 and specificity in detecting MA, VB, NVE, and NVD from 0.91-1.00. Inter-grader agreement showed FA was highest in detecting MA (89%, kappa 0.53) and NVD (89%, kappa 0.81). CFP had highest agreement in number of IRMA (75%, kappa 0.18); OCTA had highest agreement in IRMA (72%, kappa 0.63), MA (72%, kappa 0.45), and number of NVE (75%, kappa 0.47).

Conclusions: In our study OCTA outperformed FA in sensitivity and repeatability of detecting FAZ enlargement/irregularity and IRMAs. In addition, OCTA had comparable performance in detecting neovascularization. CFP overall was least able to accurately and reliably detect a variety of diabetic lesions. These findings highlight OCTA strengths in the evaluation of DR.

ABSTRACT BODY:

Purpose: Novel transgenic mice expressing fluorescent reporters associated to TRP channels have improved morphological studies of protein location. Here we report the expression of TRPM8 cold-transducing ion channel in a subset of retinal neurons. This study also aims to study the function of TRPM8 in the retina.

Methods: Retinas from TRPM8-EYFP and TRPM8-KO mice were used to detect by immunofluorescence Calretinin, Calbindin, Parvalbumin, Tyrosine hydroxylase, Choline acetyl transferase, GAD 65/67 and mGluR2. Prior to morphological analysis, WT and KO mice were examined by electroretinography (ERG) and optomotor tests to evaluate the functional role of TRPM8 in the retina. ARVO statements for the use of animals were followed.

Results: We described a population of TRPM8-positive amacrine cells with cell bodies distributed in the internal nuclear layer (INL) and ganglion cell layer (GCL), forming two densely packed neuropil layers coincident with ChAT+ sublayers 2 and 4 of the inner plexiform layer (IPL). Retinal amacrine cells from TRPM8-KO mice did not express TRPM8 protein or mRNA and were less numerous than in WT mice. Electroretinographic analysis showed alterations in oscillatory potentials and b-wave in KO mice. Optomotor test showed impaired movement discrimination in KO mice compared with WT.

Conclusions: A subtype of amacrine cells expressing TRPM8 channels has been identified. It appears unlikely that TRPM8 channels expressed by these neurons are involved in cold detection. In contrast, the expression of ChAT and the alterations in oscillatory potentials strongly suggest that about 60% of these cells may be starburst-like cells and could be involved in directional selectivity.

TITLE: Three Year Outcomes from the PALADIN Phase IV Study: Predictive Value of Prior Steroid Challenge and Intraocular Pressure Outcomes

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Fuller, Texas Retina Associates, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Christopher Fuller: Commercial Relationship(s);Code C (Consultant/Contractor):Alimera, Iveric Bio, Novartis;Code I (Personal Financial Interest):Lineage Cell Therapeutics

ABSTRACT BODY:

Purpose: A steroid challenge is mandated prior to the use of the 0.19 mg fluocinolone acetonide implant (FAc), however it is unclear which steroid is superior in identifying intraocular pressure (IOP) risk. Here we looked at the positive predictive value (PPV) of the steroid challenge by quantifying the incidence of IOP response post-FAc. FAc is indicated for the treatment of diabetic macular edema in eyes that have previously been treated with a course of corticosteroids without clinically significant rise in IOP. We computed the PPV of the steroid challenge for the full population but also for eyes that received 1 or > 1 dexamethasone implant (DEX), the most used steroid for challenge. The time course of IOP over 36 months (M) and visual acuity outcomes were also determined.

Methods: Full analysis population includes 202 eyes from 159 patients enrolled with CI-DME that received FAc and were followed for up to 36M. Subjects were followed at day 1, week 1, 2M, and quarterly from 3M up to 36M. PPV was calculated by computing the percentage of eyes whose IOP remained ≤ 25 mmHg at any time (Max PPV) or by the 36M time point (Last-PPV) post-FAc who also passed the steroid challenge (≤ 25 mmHg post challenge) pre-FAc.

Results: The Max PPV of all eyes was 78.0% with the Last PPV being 96.9%. For eyes with 1 DEX or > 1 DEX Max PPV values were 85.7% and 68.3%, and Last PPV values were 98.7% and 96.3% respectively with twice as many eyes receiving only 1 Dex prior to FAc. 20.3% of eyes received IOP lowering medication with a peak mean increase in IOP of 2.12 mmHg at 9M ($p<0.0001$) and 0.88 mmHg (NS) at 36M. Over the course of 36M, 87% of eyes had IOP ≤ 20 mmHg, 97% had IOP ≤ 25 mmHg, and 99% had IOP ≤ 30 mmHg. Eyes that received any prior steroid challenge or prior DEX all gained vision by 36M (+4.5 letters, $p<0.02$; +12.7, NS).

Conclusions: The steroid challenge pre-FAc is highly predictive of the IOP response post-FAc and not dependent on steroid choice or number of Dex. This is evident by the small change in mean IOP of the full population and that 97% of eyes had IOP ≤ 25 mmHg over the 36M post-FAc. Similarly, the steroid choice had little impact on visual acuity gains at 36 months with the full population experiencing significant vision improvement by nearly a line and eyes receiving a DEX challenge were able to maintain vision.

ABSTRACT BODY:

Purpose: Created human corneal endothelial cell (HCEC) layers or sheets aimed for the revaluation of a degenerated corneal endothelium, but mostly failed in the clinical validation due to poor mechanical stability. The immature Descemet membrane in bioengineered grafts is the main obstacle to their clinical transition. Human corneal endothelial cells have poor extracellular deposition properties in vitro. The creation of an artificial Descemet membrane could resolve this issue, but a high collagen and laminin content, as well as 16±3 microns thickness, require advanced bioengineering techniques.

Methods: We utilized peptide-functionalized, fully synthetic “smart” cell culture carriers to culture primary human MSC, which have high ECM deposition properties. Macromolecular crowding with Ficoll was used to enhance ECM secretion. Cells were cultured for ten days and removed by the diluted ammonium hydroxide solution. The formed membrane was reseeded with various cell types to validate cell adhesion and proliferation. After the confluent cell layer formation, the culture carrier was subsequently enzymatically degraded to release free-floating bioengineered Descemet membrane with attached cell layer, which was validated with various DMEK cannulas by mimicking in lab transplantation experiments

Results: The microscopic and cell staining analyses revealed that cell to cell and cell-to-matrix contacts were impaired. We utilized peptide-functionalized, fully synthetic “smart” cell culture carriers to culture primary human MSCs, which have high ECM deposition properties additionally enhanced with Macromolecular crowding. Cells were cultured for 10 days and removed by ammonium hydroxide solution. The formed bioengineered Descemet membrane was reseeded with cell types to validate cell adhesion and proliferation. After the confluent cell layer formation, the culture carrier was subsequently enzymatically degraded to release free-floating bioengineered Descemet membrane with attached cell layer, which was validated with various cannulas by mimicking in lab transplantation experiments has not impacted the implant integrity and cell viability

Conclusions: This proposed bioengineering technique has allowed, for the first time, the formation of endothelial lamella tissue with a bioengineered Descemet membrane which is shown to stabilize surgical implantation in model Descemet membrane endothelial keratoplasty DMEK experiments.

ABSTRACT BODY:

Purpose: To determine long-term surgical outcomes of Glaucoma Drainage Implants for patients with low to normal preoperative intraocular pressures

Methods: The retrospective cohort study included patients requiring Glaucoma Drainage Implants (GDI) with preoperative Intraocular Pressures (IOP) less than 19 mmHg from March 2006 to May 2017. Patients with at least 1-year follow-up in the post-operative period were included. Demographic and clinical data were collected at the preoperative and postoperative visits for up to 7 years. Surgical failures were defined as eyes that required reoperation or progressed to no light perception

Results: 46 eyes of 45 patients met inclusion criteria. Mean patient age was 66.5±13.2 years old, and mean follow-up duration was 37.3±26.5 months (range: 12-84). 9 (18.7%) eyes experienced surgical complications: 3 (33%) inflammation, 3 (33%) flat anterior chamber, 1 (11%) hypotony (without any hypotony maculopathy), 1 (11%) exotropia/hypertropia. Among all 46 eyes included, 13 (28.2%) faced failure, all of which were due to the need for reoperation and revision (n=12, 92.3%) or removal (n=1, 7.6%) of the tube shunt. Unlike SLT, ALT, CPC, vitreoretinal, and corneal surgeries, a history of a previous trabeculectomy was significantly associated with a higher risk of failure (OR:3.938, p=0.046). Moreover, those with a higher MD/year loss rate had greater chances to experience GDI failure (p=0.036). Mean IOP ranged from 13.3±3.2 to 14.9±4.5 mmHg at the preoperative visit and each follow-up visit for up to 5 years (p>0.05 for all), respectively. Humphery 24-2 visual field (VF) mean deviations (n=11) were not significantly different at -11.8±10.2 and -15.9±5.8 (p>0.05) during the most recent preoperative and postoperative visits, respectively. Moreover, the mean annual progression rate was different at -2.6±2.0 and 0.23±0.67 for preoperative and postoperative VF loss (p=0.007), indicating that the intervention slowed down the pace of VF loss at 0.53 ± 1.4 MD/year. Nonetheless, the total number of medications used by the patients significantly reduced from 3.1 ± 3.5 preoperative to 1.7 ± 1.1one year postoperative (p=0.036).

Conclusions: Unchanged IOP, as well as slower postoperative mean VF loss progression rate reported in this study, implies the significant effectiveness of tube shunt placement in controlling glaucoma in patients with low to normal IOP.

TITLE: Subthreshold Micropulse Laser Treatment in Diabetic Macular Oedema

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Bedan, F. Zacharaki, M. Rashsad, S. Morgan, F. Carr, Ashford and Saint Peter's Hospitals NHS Trust, Chertsey, Surrey, UNITED KINGDOM|

Commercial Relationships Disclosure: Aseel Hamoud Bedan: Commercial Relationship: Code N (No Commercial Relationship) | Fani Zacharaki: Commercial Relationship: Code N (No Commercial Relationship) | Mohamed Rashsad: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Morgan: Commercial Relationship: Code N (No Commercial Relationship) | Francis Carr: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the effect of micropulse MP laser treatment in patients with diabetic macular oedema DMO over a three months period.

Methods: it's a retrospective study of 80 patients with DMO, these patients are outside the treatment criteria for anti-VEGF injections, that's to say their best corrected visual acuity BCVA is better than 6/12, and/or the central macular thickness CMT is less than 400 micrometre. We measured there BCVA, CMT before and three months after MP laser treatment. We used coloured photographs, fundus autofluorescence FAF, and optical coherent tomography OCT to highlight and marks left on the retina after treatment.

Results: At three months 43 of the patients improved their BCVA, 25 worsened. CMT showed improvement in 43 of the patients and worsened in 36. Retreatment was not done on any of them using the 3 months. No one of the patients had any laser scars or marks detected on biomicroscopy, FAF or OCT scans.

Conclusions: MP laser treatment is an effective, affordable way of treating patients with DMO not meeting the treatment criteria of anti-VEGF injections.

ABSTRACT BODY:

Purpose: Nowadays, scientists are equipped with robust tools to induce genetic mutations in animal models to advance the understanding of disease mechanisms. The purpose of this work is to enable the evaluation of the outcomes of these genetic modifications and follow up these processes over time on a single specimen using advanced optical imaging techniques.

Methods: An integrated optical coherence microscopy (OCM) and dual-channel fluorescence microscopy (DCFM) system was developed to simultaneously co-register the reflectance and fluorescence signals from the cornea of transgenic mouse models. OCM was equipped with a broadband source with a central wavelength at 850 nm and FWHM of 165 nm. DCFM was designed with two excitation peaks at 473 nm for Tdtomato and 561 nm for green fluorescent proteins (GFP). A conditional knockout mouse that expresses both tdTomato and GFP in the corneal stroma was engineered to evaluate the system performances. Reflectance and fluorescence signals were registered simultaneously at a given plane of focus in the corneal stroma. However, unlike OCM, DCFM does not possess an intrinsic depth-sectioning capability. Therefore, subsequent acquisitions with DCFM alone were performed by z-scanning the sample with a step size of 2 μm to evaluate the axial resolution of DCFM.

Results: The system achieved the simultaneous co-registration of reflectance and fluorescence signals with a lateral resolution of 2 μm and speed of 250kHz line rate. OCM achieved an axial resolution of ~2 μm in the cornea.

Conclusions: The custom multimodal system was evaluated on corneal imaging of a transgenic mouse. Future work will focus on enhancing the contrast detection and depth-sectioning of DCFM.

ABSTRACT BODY:

Purpose: Emerging data link the gut microbiome with neovascular age related macular degeneration (nAMD) and choroidal neovascularization (CNV), its hallmark lesion. Our team has previously described how the microbial organ modulates the retinal expression of genes/pathways associated with nAMD such as vascular endothelial growth factor (VEGF), peroxisome proliferator-activated receptor-gamma coactivator (PGC)-1alpha and hypoxia-inducible factor (HIF) 1 pathway. To further confirm the effects of the gut microbiome on nAMD, we compared the laser-induced CNV formation between germ-free (GF) mice and specific pathogen free mice (SPF).

Methods: Male GF C57Bl/6 mice were bred/kept in sterile isolators in the UChicago Gnotobiotic Facility. Age/gender-matched SPF C57Bl/6 mice were used as control. Around 16 weeks of age, mice underwent laser photocoagulation (power 120mW/duration 0.1 sec/50um spot size, Argon 532 nm, Iridex OcuLight GL) using our specialized sterile protocol for GF mice and conventional protocol for SPF mice. Choroidal flatmounts were immunostained with isolectin IB4 for CNV and IBA-1 for activated microglia. Images were taken using a Leica-SP5 confocal microscope. CNV and IBA-1 signal were analyzed with Image-J software and data were analyzed with R Studio. Sterility of GF mice was checked weekly with cultures and PCR.

Results: PCR and cultures were negative before and after the laser sessions confirming GF sterility. GF group showed decreased CNV size by 35% (12,940.05um^2±5,627um^2, n=9 vs 19,873.39um^2±13,336um^2, n= 20, P= 0.0345) but had similar CNV formation rate compared to SPF group (92% vs 94% respectively). Number of IBA-1 positive activated microglia within 100um outside the lesion was decreased in the GF mice (5.36 and ± 4 vs 9.03 ± 5, P = 0.03). However, IBA-1 signal within CNV lesion was similar between the two groups (55.66 ± 2.79 vs 55.86 ± 6.55, P > 0.05).

Conclusions: These results, together with the RNA-seq data previously obtained, suggest that the microbial organ may have a considerable influence on the development of nAMD lesions. The GF laser-induced CNV model allowed us to eliminate other factors such as antibiotics showing the direct effects of the overall microbiome over the CNV formation. Further studies are needed to determine which microbes, either protective or pathogenic, have the highest impact on the development of nAMD and the mechanisms involved.

ABSTRACT BODY:

Purpose: Beijing Hyperopia Reserve Study is a prospective observational study to investigate 3-years trajectory of the hyperopia reserve elimination in a kindergarten-based sample of Chinese children 3 through 6 years of age in an urban city, Beijing. The baseline data was collected in 2020. Parental myopia was associated with a high risk of early-onset myopia. In addition, myopia and high myopia seem to have different patterns of inheritance, and more severe myopia leads to an increased risk of myopia in children aged 12 to 15 years old. Limited data of those associations is shown in children before the onset of myopia. Hyperopia reserve is a refractive status that precedes myopia and attracts wide attention both in parents and clinicians. We conducted this study to explore the impact of severity of parental myopia on hyperopia reserve status in Chinese pre-school children.

Methods: The study enrolled 2111 pre-school children from 22 randomly selected kindergartens including 1011 girls (2022 eyes) and 1100 boys (2200 eyes). Among them, 494, 844, 500, 273 children were 3, 4, 5, 6 years old. All children were taken cycloplegic refraction by using cyclopentolate 1%. Refraction was recorded in spherical equivalent, appreciated as hyperopia reserve. Parents were asked to complete a questionnaire about the severity of refractive status (normal; mild myopia <-3D; moderate myopia ≥-3D and≤-6; high myopia >-6D) and near/outdoor activities time and reading habits.

Results: The mean hyperopia reserve was 1.11±0.97 diopter and the mean axial length was 22.3±0.7mm in all children. In total, 90.7% of children had at least one myopic parent. There was a descending trend of hyperopia reserve and axial length with increasing severity of parental refractive status (Fig a and b). It is noted that the mean axial length in children in mild-high, mod-high, and high-high was beyond the average of the whole population (Fig b). The hyperopia reserve was correlated with neither indoors (P=0.631) nor outdoor activity time (P=0.330).

Conclusions: More severe myopia in parents was associated with less hyperopia reserve in preschool children. The children with highly myopic parents have longer axial lengths and may have higher risks of being myopia.

ABSTRACT BODY:

Purpose: Defects in primary cilia and ciliary signaling are associated with an array of neurodegenerative diseases. Advanced age is a primary risk factor for many neurodegenerative diseases, including age-related macular degeneration and glaucoma. Primary cilia are sensory organelles that transmit and regulate various cellular communication pathways, including Sonic hedgehog and Wnt signal pathways. Astrocytes and neurons are recognized to form primary cilia in the central nervous system (CNS). While many studies have examined cilia in photoreceptors and CNS neurons, there are few studies based on the role of primary cilia in astrocytes in the anterior visual pathway. This study assessed ciliary frequency (ration of ciliated cells) changes in aged astrocytes within the mouse retina and optic nerve.

Methods: Three- and 20-month-old C57/BL6 mice were used in the study. The globes and optic nerve, including the optic chiasm, were collected and immunostained for cilia markers. Retina whole-mounts were immunostained with astrocytes marker (GFAP antibody) and ciliary markers (Arl13b and gamma-tubulin antibody). Confocal images were captured and analyzed per retina (2 central, 2 middle, 2 peripheral) at high magnifications. The anterior optic nerve and optic chiasm in longitudinal frozen sections were obtained and immunostained with an astrocytic nuclear marker (Sox9 antibody), myelin basic protein (MBP) and ciliary marker (Arl13b antibody). Anterior-to-posterior optic nerve sections were quantified, including the optic nerve head, optic lamina, myelinated region, pre-chiasm, chiasm, and post-chiasm. Statistical analysis was performed using One-way ANOVA and the Student’s t-test.

Results: In mouse retina, most astrocyte ciliation is observed in 3-month-old mice among all regions. Aged retinal astrocytes showed a significant reduction in ciliation in each region ($P<0.05$, Student t-test). In the optic nerve, chiasm, and post-chiasm regions displayed higher ciliation rates in Sox9-positive astrocytes compared to anterior optic nerve in 3-month-old mice. Interestingly, ciliation in chiasm region significantly decreased compared to the anterior optic nerve in 20-month-old mice ($P<0.05$, One-way ANOVA).

Conclusions: This novel age-associated alteration was discovered in astrocyte cilium found in the mouse retina and optic nerve. These findings suggest possible involvement of primary cilia in age-associated retinal diseases.

TITLE: An Analysis of Patient Satisfaction after Double Eyelid Surgery using Social Media Reviews

SESSION TITLE: Eyecare delivery and economics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Zhou, J. Mahajan, C. Tseng, R. Henry, P.D. Langer, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Benjamin Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Jasmine Mahajan: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Roger Henry: Commercial Relationship: Code N (No Commercial Relationship) | Paul Langer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Because double eyelid surgery is often an aesthetic surgery for cosmetic purposes, patient outcomes rely heavily on qualitative measurements of satisfaction. It is important to characterize individual factors that shape patient perspectives about double eyelid surgery, as cosmetic satisfaction may translate to improved body image and self-esteem.

Methods: All reviews under the category “double eyelid surgery” on RealSelf.com were collected using an automated web crawler. Reviews were then characterized as overall positive or overall negative and given a primary categorization that defined the theme of the review and a secondary categorization if there was additional secondary reasoning for being positive or negative. The number of stars for rating different categories on a scale of 1 to 5 was also gathered.

Results: A total of 549 double eyelid surgery reviews were collected. Of the 549 total reviews, 456 (83%) were positive and 93 (17%) were negative. Among the positive reviews, the most frequently cited primary reasons were bedside manner (n=226, 50%) and aesthetic result (n=195, 43%). Among the negative reviews, the most frequently cited primary reasons were aesthetic result (n=67, 72%) and bedside manner (n=18, 19%) (Table 1). Overall, most patients (n=403, 84.3%) gave the highest overall rating of 5 stars for their doctor. The most cited reasons for a 5 out of 5 rating were “staff professionalism and courtesy” (n=220), “answered my questions” (n=216), and after care follow-up (n=210). The most frequently cited reasons for the poorest rating of 1 out of 5 were “after care follow-up” (n=21), “time spent with me” (n=21), and “doctor’s bedside manner” (n=19) (Table 2).

Conclusions: Patient satisfaction is a significant aspect of perceived success and encompasses many components like preoperative encounters, surgery experience, and the postoperative recovery course. In this study, the majority of reviews were positive most commonly due to bedside manner and aesthetic result. Negative reviews were most frequently due to aesthetic results. Our findings emphasize the importance of the multifaceted components of the clinical encounter both inside and outside the operating room. Although operative performance and final appearance are always important, preoperative and postoperative management can play a huge role in overall patient satisfaction.

TITLE: Classical complement initiator C1q mediates synapse and neuronal loss in a light damage model of photoreceptor degeneration

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Tassoni, J. Vereen, Y. Andrews-Zwilling, E. Cahir-McFarland, L. Mattheakis, T. Yednock, Annexon Biosciences, Brisbane, California, UNITED STATES|

Commercial Relationships Disclosure: Alessia Tassoni: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Vereen: Commercial Relationship: Code N (No Commercial Relationship) | Yaisa Andrews-Zwilling: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Cahir-McFarland: Commercial Relationship: Code N (No Commercial Relationship) | Larry Mattheakis: Commercial Relationship: Code N (No Commercial Relationship) | Ted Yednock: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Geographic Atrophy (GA) is an advanced form of age-related macular degeneration leading to photoreceptor death and visual loss. Increased expression of complement components has been observed in retinal tissue from GA patients. The role of C1q and the classical complement pathway in driving disease progression is under investigation. We examined expression and tissue localization of complement proteins in the retina of mice exposed to light damage and determined the potential therapeutic benefit of classical complement inhibition in this model.

Methods: Balb/c mice were exposed to white light to cause retinal damage and observed at Day 1, 3 and 7 post light exposure. Classical complement component levels were measured in retina lysates by ELISA. C1q expression in the tissue was assessed by IHC. Microglia engulfment of synapses was assessed using IMARIS software. To test the role of the classical complement pathway in photoreceptor cell damage, C1q activity was pharmacologically blocked by intravitreal injection of a C1q inhibitory antibody. Retina specimens from GA patients were procured from the San Diego Eye Bank.

Results: There was progressive loss of photoreceptor synapses and cell bodies, as well as an increase in microglial cells across the outer plexiform (OPL, synapses) and outer nuclear layers (ONL, cell bodies) in mice exposed to light damage. C1q expression was induced in microglia and was localized on photoreceptor synapses and cell bodies following light damage. There was a significant correlation between levels of C1q in the OPL and ONL and photoreceptor synapse and cell body loss. C1q-tagged synapses were engulfed by microglial cells upon damage suggesting a causal relationship. Treatment with a C1q inhibitory antibody normalized complement component levels. Preliminary evidence showed reduced photoreceptor synapse and cell body loss, and reduced inflammation. We confirmed C1q deposition on photoreceptor synapses in human GA retina tissue suggesting that this mechanism may be operative in humans.

Conclusions: We provide first evidence of C1q deposition on photoreceptor synapses in a light exposure model of retinal damage in mice and in human GA tissue. Preliminary results suggest that inhibiting C1q protects against photoreceptor neuron damage. A Phase 2 study with a C1q inhibitory antibody is ongoing in GA patients (clinical trials.gov NCT04656561).

TITLE: sptPALM-based trafficking analysis of GPCRs in primary cilia

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Malhotra, P.D. Calvert, Ophthalmology and visual sciences, SUNY Upstate Medical University Hospital, Syracuse, New York, UNITED STATES|

Commercial Relationships Disclosure: Himanshu Malhotra: Commercial Relationship: Code N (No Commercial Relationship) | Peter Calvert: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Super resolution microcopy techniques have pushed the limits of optical imaging to unprecedented spatial resolution. A frontier in super-resolution microscopy is its utilization in live cells or organisms. A few studies have examined the trafficking of GPCRs in living primary cilia using sparse individual molecule labeling, e.g., with Qdots. However, many questions remain regarding GPCR movement in primary cilia as well as photoreceptor ciliary outer segment that this approach cannot adequately address due to the low numbers of GPCRs observed. We thus are developing live cell sptPALM (single particle tracking photoactivation localization microscopy) approaches for mapping the motion of hundreds to thousands of individual GPCRs within a single cilium.

Methods: Dynamics of the GPCR, somatostatin receptor 3 (SSTR3), was examined in hTERT-RPE1 cell primary cilia by sptPALM. hTERT-RPE1 cells stably expressing SSTR3-mEos4b were generated using lentiviral transduction. Upon starvation, hTERT-RPE1 cells expressing SSTR3-mEos4b generates pocketed cilia where SSTR3-mEos4b is enriched. sptPALM imaging was performed using a Nikon microscope equipped with an iLAS2 ring TIRF illuminator. Sparse photoswitching of mEos4b specifically in the cilium was achieved by dim 405nm laser focused to the diffraction limit and positioned by galvanometer mirrors. Activated molecules were excited with widefield 561nm illumination and videos were acquired on an EMCCD camera at 50 frames per second. Videos were analyzed using TrackMate (Fiji) and MATLAB scripts developed in-house

Results: Hundreds to thousands of individual GPCR molecules were tracked within single cilia using sptPALM. Various parameters of these movements were mapped onto each cilium. Analysis of mean squared displacement as a function of time revealed that GPCR dynamics acquired using sptPALM corresponded to previous results with Qdots. Diffusion coefficients segregated into at least two groups when analyzed by histogram, agreeing with our previous work suggesting that ciliary membranes possess F-actin delimited corrals.

Conclusions: We show that our sptPALM approach is capable of tracking the dynamic of thousands of GPCRs in a single cilium within minutes, at high temporal and spatial resolution. Thus, sptPALM will allow us to map the biophysical properties of membranes and proteins of primary cilia, and photoreceptors, with unprecedented spatial resolution and high throughput.

Commercial Relationships Disclosure: Michael Dorr: Commercial Relationship(s);Code I (Personal Financial Interest):Adaptive Sensory Technology, Inc.;Code P (Patent):Adaptive Sensory Technology, Inc.;Code E (Employment):Adaptive Sensory Technology, Inc. | Yukai Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Luis Lesmes: Commercial Relationship(s);Code I (Personal Financial Interest):Adaptive Sensory Technology, Inc.;Code P (Patent):Adaptive Sensory Technology, Inc.;Code E (Employment):Adaptive Sensory Technology, Inc. | Zhong-Lin Lu: Commercial Relationship(s);Code I (Personal Financial Interest):Adaptive Sensory Technology, Inc.;Code P (Patent):Adaptive Sensory Technology, Inc., The Ohio State University

ABSTRACT BODY:

Purpose: Visual acuity (VA) is measured with the ETDRS standard in clinical trials. Snellen remains the real-world standard, although Snellen VA is typically worse by 6 ~ 12 letters (0.12 ~ 0.24 LogMAR). In this study, we modeled ETDRS-Snellen discrepancies for 163 observers from Kaiser (2009) to enable better translation between the VA standards.

Methods: We used a VA behavioral function to simulate VA behavior for 27 observers with VA threshold τ from -0.3 to 2.3 LogMAR and VA-dependent range 0.253 + 0.185 VA LogMAR (Zhao et al. 2021). We scored VA behavior using ETDRS and Snellen rules (Kaiser, 2009). From repeated simulations of each observer, we computed the mean and standard deviation (SD) of VA scores and modeled ETDRS-Snellen score pairs using maximum likelihood.

Results: For the two charts, Figure 1 shows the bias (deviation from identity line) and variability (SD) of VA scores. Small biases observed when τ < 1.0 LogMAR increased significantly as VA worsened: bias > 0.20-0.50 LogMAR as τ > 1.0 LogMAR. Likewise, variability increased for worse VA: SD up to 0.15 for ETDRS and 0.19 for Snellen. Results from each simulated observer were used to construct the probability distributions for ETDRS-Snellen score pairs (Figure 2A). They were used to successfully model all the ETDRS and Snellen scores (Figure 2B) in Kaiser (2009) ($p > .05$ for all differences between observed scores and model predictions).

Conclusions: Using a VA behavioral function, we successfully modeled discrepancies between ETDRS and Snellen scores from a large sample of subjects with a wide range of VA scores. The model can be used to translate between VA measured in trials and real world.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic prompted efforts to encourage social distancing and minimize non-urgent in-person eye care. Here, we report the outcomes of a teleophthalmology program for diabetic retinopathy screening at an integrated health system in California that was expanded during the pandemic.

Methods: We performed a retrospective review of patients who underwent remote retinal imaging as part of a teleophthalmology program for diabetic retinopathy (DR) screening using Current Procedural Terminology (CPT) codes 92227 and 92228 at the University of California, Davis Health system between May 31st, 2019 and June 8th, 2021. Retinal images were captured at primary care locations using a Topcon NW400, Nikon RetinaStation, or Optos Primary fundus cameras, and image grading were performed by trained ophthalmologists or optometrists using a store-and-forward method. Patient records were reviewed to collect demographic, follow-up, and clinical outcomes information.

Results: During COVID19 pandemic, the teleophthalmology program screened 570 individuals (mean age 63.2 ± 13.7). There was a significant increase in the number of patients screened per month prior to and following the COVID-19 lock-down in March 2020 (5.0 ± 3.1 patients screened per month prior to and 39.1 ± 34.8 patients per month following, P = 0.0004). Among these, 204 patients received a recommendation for in-person eye care referral, of which 127 received a referral to the UC Davis Eye Center, 85 appointments were scheduled, and 82 patients were followed in person, with a median time of 108 days between screening and in-person follow-up. Follow-up rates were generally lower during the initial months after the pandemic and increased over time. Among the patients who followed in person (mean age 63.9 ± 13.8), 10% of eyes had mild non-proliferative DR (NPDR), 5% had moderate NPDR, 3% had severe NPDR, 2% had PDR, and 4% had diabetic macular edema (DME), with similar proportions before and after the COVID-19 lockdown.

Conclusions: Expansion of a teleophthalmology program during the COVID19 pandemic demonstrated improved DR screening rates, increased referrals, and improved follow-up for diabetic eye care at an integrated health system in Northern California.

ABSTRACT BODY:

Purpose: Although previous studies have shown a regression in corneal neovascularization (CoNV) after intrastromal bevacizumab injection, more efficient or alternative treatment options are still needed and the effect of intrastromal aflibercept injection on CoNV in humans has not been studied. We performed a retrospective, observational clinical study to investigate the effect of a single intrastromal injection of aflibercept on eyes with CoNV.

Methods: This retrospective study included 17 eyes of 17 patients with CoNV who underwent intrastromal injection of a single dose aflibercept (Eylea 40 mg/mL) at a single institution. 0.1 mL of aflibercept was administered into the stromal areas with apparent neovascularization (NV) by allocating the dose to each quadrant with NV until the observation of stromal whitening (max. 0.025 mL/quadrant). Slit lamp photography, best corrected visual acuity, and intraocular pressure of patients was recorded. The ratio of CoNV area to the entire corneal area was calculated using ImageJ by a masked observer. The examination findings of the patients 30 and 60 days after injection were compared to those at the baseline visit.

Results: Among 17 patients with CoNV, 15 patients (88.2%) were male and 2 (11.8%) were female. Four patients (23.5%) had a history of penetrating keratoplasty. The mean age of the patients was 52.9±12.1 years. The mean CoNV area (37.0±18.1%) decreased significantly 30 days (25.3±14.6%, p=0.0.18) and 60 days after aflibercept injection (21.4±14.3%, p<0.001). No significant systemic or ocular adverse events were observed during the follow-up.

Conclusions: Within the limitation of this retrospective study, a single dose of intrastromal aflibercept injection provided a significant reduction in the CoNV. However, further prospective randomized controlled trials with a longer follow-up period are needed for extending the results of this study.

TITLE: A Two-Year, Phase 1 Study to Evaluate the Efficacy of Oral Curcumin on Drusen Volume

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.A. Knepper, N.J. Volpe, S. Aman, Z. Zaparackas, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|P.A. Knepper, N. Pfahler, I. Bielskus, Ophthalmology and Visual Sciences, University of Illinois at Chicago College of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Paul Knepper: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Pfahler: Commercial Relationship: Code N (No Commercial Relationship) | Indre Bielskus: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Volpe: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Aman: Commercial Relationship: Code N (No Commercial Relationship) | Zibute Zaparackas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Advanced age-related macular degeneration (AMD) is a leading cause of vision loss. The presence and size of drusen are risk factors for the development of advanced AMD and loss of central vision. Although the cause of drusen remains unclear, individuals with larger drusen are more likely to develop advanced AMD. In this study, we evaluated the effect of oral curcumin on drusen volume and the development of advanced AMD over two years in AMD patients with drusen ≥125 μm at baseline using a new technique of tracking changes in individual drusen over time.

Methods: AMD participants with drusen ≥125 μm and without geographic atrophy or choroidal neovascularization (n=15) were recruited from the office of Zaparackas and Knepper, Ltd. in Chicago, IL after IRB approval and informed consent. Participants received curcumin orally at a dose of 2660 mg/day for two consecutive years. Optical coherence tomography (OCT) was used to acquire retinal photographs which were analyzed manually using ImageJ software. Drusen volume was measured for all macular drusen ≥63 μm and was recorded in mm^3. Macular regions were defined using the 1, 3, and 6-mm grid. Individual drusen were classified by size at baseline as 63-124 μm, 125-249 μm, or ≥250 μm and tracked over time.

Results: After two years, total drusen volume decreased significantly from 0.0253 (±SD 0.015) to 0.0220 (±0.013) mm^3 (-13.1%, p=0.01). Drusen ≥250 μm at baseline decreased in volume from 0.0117 (±0.0078) to 0.0095 (±0.0073) mm^3 (-18.9%, p=0.004). Drusen 125-249 μm at baseline decreased in volume from 0.0128 (±0.0105) to 0.0110 (±0.0089) mm^3 (-14.6%, p=0.09). All drusen ≥125 μm (AREDS definition of large drusen) decreased from 0.0215 (±0.0142) to 0.0183 (±0.0131) mm^3 (-14.8%, p=0.008). Medium drusen 63-124 μm did not significantly change (-3.4%, p=0.74). None of the 15 participants developed advanced AMD (geographic atrophy or choroidal neovascularization) during the study and no serious adverse events were recorded.

Conclusions: Drusen volume decreased significantly in AMD participants taking curcumin for two years. Larger drusen at baseline exhibited larger decreases in volume. None of the participants developed advanced AMD during the study. These results are the first to identify a change in drusen volume by categorizing and tracking individual drusen over time. Curcumin may be a safe and efficacious method to reduce drusen volume and risk of AMD progression.

ABSTRACT BODY:

Purpose:

We report further details of a mouse model for neurofibromatosis type 1 (NF1) and optic pathway glioma (OPG) formation that exhibits developmental abnormalities of retinal electrophysiology distinguishable from OPG formation per se. Underlying mechanisms may help explain variable visual loss among children with NF1 and OPGs and lead to improved diagnosis and treatment methods.

Methods: We refined previous analysis of relationships among visual behavior, anatomic abnormalities, and electrophysiologic activity of retinal ganglion cells (RGCs) recorded by in vitro multielectrodes in transgenic mice with neurofibromin (Nf1)-deficient glial precursors (NF1-OPG) and littermate controls. We focused on 1) early developmental abnormalities (postnatal day 11 (P11), P14, P21, and P35); and 2) retinotopic distribution of RGCs vs. their activity. We emphasized correlations among previously described patterns of RGC loss; retrobulbar hypomyelination; inter-subject and -eye differences; in vivo estimates of vision (optomotor responses, OMR) and retinal/optic nerve anatomy (optical coherence tomography, OCT); and optic nerve/chiasm histology.

Results: Development – Prior to first eye opening, “waves” of spontaneous RGC activity are less robust in NF1-OPG mice. Retinotopic distribution – RGC density partially correlates with electrophysiologic activity, but fewer RGCs are active in NF1-OPG mice, and activity levels do not predict patterns of RGC loss. Declines in OMR-estimated visual acuity and retinal thinning on OCT correlate with RGC survival, but with moderate variability among subjects and eyes.

Conclusions: Our findings support the existence of multiple anatomic and physiologic effects of Nf1-mutant glial precursors, several preceding OPG formation. These features may better explain vision loss in many young NF1-OPG patients that remains incompletely explained by readily observed OPG features. Future longitudinal studies may refine our understanding of the nature and relative pace of these distinct mechanisms, leading to improved identification of patients at higher risk for visual loss and to more targeted treatments.

ABSTRACT BODY:

Purpose: There is increasing evidence to support a vascular role in the pathophysiology of glaucoma with one element possibly involving insufficient or erratic blood supply to the proximal optic nerve and retina. The α1 subunit of soluble guanylate cyclase (GC1), an enzyme involved in a major pathway of blood flow regulation, has been implicated through human GWAS studies with glaucoma incidence. Because aged GC1 knockout mice exhibit characteristics common to glaucoma, we sought to investigate whether GC1 signaling affected retinal morphology and integrity of the neurovascular unit, which could contribute to the neurodegeneration observed in the model.

Methods: Age-matched 3- or 15-month GC1-/- and WT mice were utilized throughout the study. Using immunohistological staining and fluorescein angiography, we assessed retinal vasculature and astrocytic morphology. We implemented the REAVER analysis tool to quantify multiple blood vessel properties such as length, density, and diameter. We also manually quantified the length of higher-order branches. Custom written code was also used to quantify regional density of GFAP across wholemount retinas as well as assess radial complexity of the GFAP distribution through Scholl analysis.

Results: Aged GC1-/- mice exhibit peripheral retinal vessel dilation compared to WT (33.1 ± 6.1 μm vs. 28.4 ± 6.3 μm diameter; $p = 0.015$) as well as an increased frequency of shorter capillary branches ($p<0.001$). There is evidence of blood-retinal-barrier (BRB) breakdown and vessel leakage in aged GC1-/- mice that is absent in age-matched WT mice. GC1-/- mice show aberrant isolectin-B4 staining in a debris-like pattern and increased leakage of fluorescein into the retina by fundus imaging. Retinal vessel compromise coincided with an abnormal morphological astrocyte phenotype; focal regions of GC1-/- retina exhibit a highly disorganized distribution of astrocytes, with areas of dense “matted” astrocytic networks surrounding major blood vessels as well as increased global GFAP-positive density across the retina.

Conclusions: Together our results indicate that dysfunctional GC1-cGMP signaling leads to alterations in retinal vessel and astrocyte morphology with age, which may lead to interruption of blood flow to exacerbate or trigger neurodegeneration. Our results suggest that functional cGMP signaling is important for maintaining the BRB and retinal astrocyte morphology.

ABSTRACT BODY:

Purpose: Mitochondrial (Mt) damage precedes histopathological abnormalities in diabetic retinopathy (DR). Recent studies show that Mt transfer can rescue cells from bioenergetic abnormalities and cell death. This study in DR cell culture and animal models examines whether i) Mt transfer can normalize bioenergetics of retinal cells and ii) if bone marrow derived mesenchymal stem cells (MSC) represent a source of Mt for transfer to damaged retinal endothelial cells (REC).

Methods: BREC, hMSC, and ARPE19 cells were cultured using established protocols. ARPE19 cells were depleted of mitochondria by culturing in media containing 50 ng/ml ethidium bromide and 50 µg/ml uridine for up to six passages. Mt were labeled using rLV-EF1-EGFP infection. Mt were isolated using differential centrifugation protocols. Mt haplogroups were analyzed at the sequence depth ID 30,000; range 1,000 to 100,000. Respiratory activity was assessed using a custom microfluidic respirometer. Retinal ischemia-reperfusion (I/R) mouse model was used to assess Mt transfer in vivo.

Results: The effect of Mt transfer on bioenergetics was assessed in Mt depleted Rho^o ARPE19 cells. ARPE19 cells have U5 mitochondrial haplogroup with high respiratory activity, however adherent Rho^o ARPE19 cells had no significant respiratory activity (0.2±0.08 pmol O_2/sec/10^6 cells). Overnight incubation of adherent Rho^o ARPE19 cells with Mt isolated from control ARPE19 cells led to progressive increase in the respiratory activity over 10 days up to 3.4±0.7 pmol O_2/sec/10^6 cells, which is equivalent to the activity of the wild type ARPE19 cells at day 10 (4.2±1.7 pmol O_2/sec/10^6 cells). Moreover, normalization of respiratory activity due to Mt transfer improved viability and increased growth rate of Rho^o ARPE19 cells. We next determined if Mt transfer occurs between vascular progenitor cells and REC in DR cell culture and animal models. BREC treated with TNFα (10 ng/ml) for 24 hrs induced tunnelling nanotube (TNT) formation and Mt transfer by non-diabetic hMSC. No Mt transfer was observed in control BREC. 4 days following injection of MSC, TNT formation and Mt transfer was observed using IHC in I/R injured, but not in the uninjured mouse eye when injected with hMSC.

Conclusions: Exogenous Mt incorporate into cellular mitochondrial networks and normalize bioenergetics of damaged retinal cells. Mt transfer is a mechanism that provides paracrine support to damaged retinal vasculature.

ABSTRACT BODY:

Purpose: The purpose of this study was to determine the effects of oxidative stress on phagocytosis, barrier function and both redox and innate immune signaling in two in vitro models of human retinal pigment epithelium (RPE) cells, human telomerase reverse transcriptase-overexpressing RPE (hTERT-RPE) and induced pluripotent stem cell-derived RPE (iPSC-RPE) cells.

Methods: Cells were grown in Dulbecco's modified Eagle's medium:F-12 + 10% FBS (with non-essential amino acids, 1% B27 supplement, 10ng/ml triiodothyronine and 100µM taurine for iPSC-RPE only) to full confluence for experiments. Cells were exposed to 50µM or 200µM tert-butyl hydroperoxide (tBHP) in media for 24 hours to induce mild or severe oxidative stress, respectively. Fluorescein isothiocyanate (FITC)-conjugated latex beads of 1µm diameter were used in phagocytosis assays to measure cell function. Actin was labeled with phalloidin-Alexa Fluor 594 and immunocytochemistry was performed to detect zonula occludens 1 (ZO-1), nuclear translocation of nuclear factor erythroid 2-related factor 2 (Nrf2) and nuclear factor kappa-light-chain-enhancer of activated B cells (NFκB) immunoreactivity. Cells were imaged with confocal microscopy (Leica TCS SP5) and image analysis was performed using ImageJ software. Transepithelial electrical resistance (TEER) measurement was conducted with an Ussing chamber system to determine RPE cell barrier function.

Results: Mild oxidative stress (exposure to 50µM tBHP for 24 hours) had no apparent effect on RPE cell size or morphology as determined by microscopy. Mild oxidative stress also had no effect on phagocytosis, but led to increases in ZO-1, Nrf2 and NFκB immunoreactivity, as well as to a 45% increase in TEER. Higher levels of oxidative stress (exposure to 200µM tBHP for 24 hours) led to changes in cell size and morphology, but did not result in cell death. RPE cells undergoing such severe oxidative stress displayed also impaired phagocytosis, altered and less organized distribution of actin and ZO-1 immunoreactivity and decreased TEER indicative of impaired RPE cell barrier function.

Conclusions: Oxidative stress induces specific structural and functional changes in cellular signaling in in vitro models of human RPE cells. These changes include an altered cellular redox homeostasis and innate immune signaling potentially contributing to adaptive functional responses in RPE cells.

ABSTRACT BODY:

Purpose: Whilst teleophthalmology has gained increasing importance during the pandemic by providing a novel way of patient-physician encounter, not all of our patients seem to benefit from this new format of access to eye-care. Exploring user perspectives and perceived barriers is crucial for avoiding digital exclusion. This study investigated patients motivation for and factors preventing them from utilizing teleophthalmology.

Methods: A 15-item questionnaire was distributed to patients attending face-to-face (F2F) appointments or video-consultations (VC) at Moorfields Eye Hospital. Questions explored participants rationale for (not) using VC, digital literacy skills, confidence online, access to technology and potential demand for support. Anonymised responses were collected and analysed.

Results: Responses were obtained from a total of 92 patients (F2F n=63, VC n=29). Key findings revealed an overall 30.4% had low confidence in diagnostic proficiency of VC. Older patients (38.9% of patients aged ≥65y vs. 14.6% of those aged 35-64y vs. 3.8% of those aged ≤34y) were less comfortable navigating online and were more likely to lack access to internet or devices required to join VC (27.8% vs. 4.2% vs. 0.0%). Avoidance of traveling long distances (51.1%), minimization of disruption of daily life (31.5%) and fast access to eye specialists (25.0%) were the main perceived benefits of VC. Younger patients (aged ≤34y) were more likely to use and prefer VC. Participants having encountered VC at least once were generally more positive about VC. 13.0% of all participants were not aware that healthcare services could be accessed remotely.

Participants (19.6%), and particularly older generations (27.8% ≥65y), felt that local community support and technology teaching sessions could bolster engagement with digital healthcare services.

Conclusions: This study found that younger patients and those who have previously used VC are more likely to prefer and benefit from using VC. Lack of digital skills, poor access to technology and low confidence in digital healthcare are factors that must be addressed to ensure that certain patient subgroups do not miss out on the benefits of teleophthalmology. Patients have expressed interest in solutions such as digital skills workshops (delivered in hospital or the community) and schemes to enhance access to the internet and devices.

TITLE: Developing Scalable Purification of Small Extracellular Vesicles Using Size Exclusion Chromatography

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Knight, B. Le, J.J. Zheng, S.X. Deng, Stein Eye Institute, University of California Los Angeles, Los Angeles, California, UNITED STATES|P. Neviani, Extracellular Vesicle Core, Children's Hospital of Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Rob Knight: Commercial Relationship: Code N (No Commercial Relationship) | Bryan Le: Commercial Relationship: Code N (No Commercial Relationship) | Jie Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Paolo Neviani: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Deng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our research group has demonstrated beneficial functional responses using extracellular vesicle (EV) EVs isolated using a polymer based technique, however this purification technique is not scalable or cGMP compliant. The purpose of this research is to evaluate size exclusion chromatography (SEC) as an alternative isolation technique for the production of functional EVs.

Methods: EVs were purified from the conditioned medium of CSSC cultures using either a) precipitation using Total Exosome Isolation Reagent (TEI; ThermoFisher) or b) SEC (qEV; Izon). EVs were examined in respect to their size using nanoparticle tracking analysis (NTA, Nanosight; Malvern), morphology by Transition Electron Microscopy (TEM) and tetraspannin expression (CD9, D81 and CD63) using ExoviewR100 (NanoView). Functional testing was carried out in RAW cells by inhibiting their inflammatory response when stimulated with LPS and in inhibiting myofibroblast formation when corneal fibroblasts are stimulated with TGFb1.

Results: EVs were purified using both TEI and qEV purification methods as determined by an increase in the Particle:Protein (P:P) purity ratio. NTA analysis demonstrated an enrichment of particles between 50-130 nm. The size was confirmed using TEM which also demonstrated cup-shaped membrane bound vesicles. TEI purification resulted in a larger modal particle size than that of SEC (85nm vs 73nm, respectively). Both purification techniques demonstrated comparable tetraspannin expression profiles that were similar to the tetraspannin profiles before purification ($P>0.05$). Functionally, it was observed that EVs were capable of inhibiting the inflammatory response of RAW Cells stimulated with LPS by 34% compared to the LPS only control as measured by IL6 and TNFa expression ELISA ($P<0.05$). EVs demonstrated comparable levels of functionality (decrease in IL-6 and TNFa expression) in this assay with no significant difference observed in potency ($P>0.05$). At this same concentration EVs demonstrated comparable potency in reducing aSMA and EDA-FN expression in primary corneal fibroblasts indicating potential inhibition of myofibroblast transdifferentiation.

Conclusions: Both polymer-based centrifugation and SEC techniques are capable of purifying sEVs from CSSC conditioned medium. Both techniques demonstrate no bias in the sEVs population purified. Therefore, SEC could be used for the scale up of sEV purification.

ABSTRACT BODY:

Purpose: The Fas/Fas ligand (FasL) system plays an integral role in the maintenance of corneal immune privilege and regulation of corneal wound healing. Previous research has shown that membrane bound FasL (mFasL) and soluble FasL (sFasL) exert opposing pro- and anti-inflammatory effects respectively in response to corneal injury. This study aims to explore the proinflammatory role of mFasL in the setting of alkali burns in mouse corneas which are sFasL deficient.

Methods: A mouse model with a deleted matrix metalloprotrease cleavage site was established to suppress the expression of sFasL, resulting in increased levels of mFasL expression systemically. To induce injury, the corneas were exposed to alkali burns. The corneas were observed for one month following injury to monitor for corneal neovascularization (CoNV), and then harvested. The collected corneas were stained for macrophage markers F4/80 and CD11b then analyzed and quantified by immunofluorescence.

Results: The mice that overexpressed mFasL showed significantly increased CoNV 14 days after alkali burn treatment compared with wild-type mice. Analysis of the harvested corneas from mFasL mice also showed an approximately 30% increase in F4/80+ and CD11b+ inflammatory cell infiltration at 1 month compared to the control group.

Conclusions: The increased CoNV and inflammatory cell infiltration observed in the corneas of mice that overexpressed mFasL suggests that mFasL plays a proinflammatory role in the cornea after injury. Considering the impact of mFasL on corneal injury and wound healing, it may serve as a potential target for therapy in corneal disease.

ABSTRACT BODY:

Purpose: The goal of this study is to compare the demographic features and clinical findings of patients who present for initial or follow up evaluation of ocular surface discomfort to a primary care optometric private practices to those who present to a tertiary care hospital-based ophthalmology clinics.

Methods: Patients were prospectively recruited in this multicenter study if they had complaints of or a history of ocular surface discomfort. Demographic information was collected, and patients competed the OSDI and Ocular Pain Assessment Survey (OPAS) and underwent a clinical examination including medical history. For each bilateral clinical measure, the worse measure was used for analysis. Results were compared using the chi square, Mann-Whitney U test, or T-test as appropriate.

Results: The average age of patients at the tertiary care sites was higher (49.8±2.5 years) than that of the private practice site (39.1±2.2; p=0.003). There was no significant difference in male/female distribution (82.4% female for tertiary care vs. 71.4% for private practice; p=0.210). There was no significant difference in the scores of the OSDI or the OPAS 24 hour eye pain intensity, 2 week eye pain intensity, or non-eye pain dimensions between the sites. Patients treated at the tertiary care sites had more medications included in their medical history [8.0 (range: 0-22) vs 0.0 (0-3); p<0.001] and a lower Schirmer's test result [6.0 mm (1-15) vs 15 (3-15); p<0.001]. The private practice sites' patients had a lower tear break-up time [3.8 sec (1.3-6.3) vs. 5.0 (0-15); p=0.006] and a worse meibum grade [1.0 (0-3) vs 0.0 (0-3); p=0.020].

Conclusions: Patients who report to tertiary care and private practice sites have similar symptom profiles. However, those who report to tertiary care clinics are older and have more extensive medical histories to consider. While both samples of patients showed reduced tear film break-up time, it appears that those who presented to the tertiary care clinics are more likely to show features of aqueous deficient dry eye disease while those at the private practice clinic showed features more consistent of meibomian gland dysfunction. As numbers of clinics and sample size increase in the NASA Study, a profile neurosensory abnormalities across this wide representation of dry eye patients will be established.

ABSTRACT BODY:

Purpose: To assess completion rate and correlation of virtual reality visual field (vFA) home monitoring in a pilot sample of experienced visual field test takers with glaucoma.

Methods: 9 Adults (mean age 60.6 years) with an established diagnosis of glaucoma were prospectively enrolled in this ongoing pilot study from a single institution. After an in-office training, participants were sent home with the VisuALL Field Analyzer (vFA; Olleyes Inc. Summit, NJ) for perimetry and the iCare Home Rebound Tonometer (TA022, Icare Oy, Vanda, Finland) for intraocular pressure (IOP) measurements. They were instructed to collect 4 IOP measurements per eye per day for 3 days, and 1 perimetry test per day over the same 3 days. The mean deviation (MD) and pattern standard deviation (PSD) values from the 3 at-home vFA tests were averaged and compared to the most recent in-office Humphrey Field Analyzer (Carl Zeiss Meditec, Dublin, CA) visual field (HVF) values using SPSS V.28 (IBM SPSS Statistics) to determine the Spearman correlation coefficient. The intraclass correlation (ICC) for MD and PSD values were also calculated for the 3 vFA perimetry tests taken at home. IOP in-clinic and at-home were compared using the Pearson correlation coefficient.

Results: Of 9 participants enrolled, 6 (10 eyes) successfully completed the protocol. 1 participant had difficulty using the devices and 2 were lost to follow-up. The Spearman correlation coefficient of the MD and PSD from vFA relative to the HFA was 0.758 ($p=0.011$) and 0.867 ($p=0.001$), respectively. ICC values for the 3 vFA perimetry tests taken at home were 0.918 ($p<0.001$) for MD and 0.955 ($p<0.001$) for PSD. The average of the last 5 IOP measurements in-clinic compared to the average of all the at-home measurements yielded a Pearson correlation coefficient of 0.954 ($p<0.001$).

Conclusions: Home monitoring with vFA and rebound tonometry is feasible and may provide clinically useful data to help manage glaucoma patients remotely.

ABSTRACT BODY:

Purpose: As demand for eye services is projected to rise by 30-40% in the next two decades, long-term solutions must be sought to continue to provide quality care. Telemedicine is an option for specialities reliant on history and observation, such as Oculoplastics, of which benign eyelid lesions make up most referrals. We undertook a retrospective analysis of 974 patients referred for benign eyelid lesions to our tele-oculoplastic clinic. By assessing the efficacy of a hybrid synchronous-asynchronous teleconsultation model, we describe a new streamlined approach to our Benign Eye Lesion Pathway (BELP).

Methods: We retrospectively collected data from 'OpenEyes' electronic patient records for patients who went through the BELP service from July 2020 to July 2021. Patients sent from primary care with benign lid lesions were booked to a live video-consultation using 'Attend Anywhere'. Prior to this, they completed an online questionnaire and uploaded a photograph of the lesion. Patients requiring minor surgery were booked in during the video consultation and consented virtually. We assessed time efficiency, accessibility, affordability and theatre utilisation of the BELP service. To analyse safety, 50 discharged patients were monitored in surveillance clinic to ensure correct diagnosis and management.

Results: Of 974 patients, 558 (57.2%) were listed for surgical procedure from virtual assessment, 232 (23.8%) were discharged and 180 (18.5%) required follow up. Of those requiring follow up, 65 (36.1%) were booked face-to-face and the remainder virtually. The DNA rate was 2.57%, compared with an average of 8.7% for first face-to-face outpatient appointments. Theatre utilisation was efficient, with only 36 (5%) of the patients listed for surgery not proceeding on the day. 58.6% of diagnoses made virtually were accurate with histological findings. No cases deemed benign on remote assessment came back atypical or malignant. There was no significant change in management plan in any case.

Conclusions: The BELP service is a safe alternative to face-to face consultation, leading to efficient theatre utilisation, reduced cancellations, and elimination of travel time and cost for the patient. If clinician satisfaction and issues regarding accessibility to digital infrastructure are explored, telemedicine could be an effective service for the non-urgent biopsy pathway.

ABSTRACT BODY:

Purpose: To develop an automated segmentation algorithm for quantifying the outer-retinal layer (ORL) thickness in 3D OCT scans.

Methods: Eyes were imaged with swept-source OCT (SS-OCT, PLEX® Elite 9000; ZEISS, Dublin, CA) using a 6 x 6 mm scan pattern. ORL is defined from the upper boundary of the outer plexiform layer (OPL) to the retinal pigment epithelium (RPE) layer. To segment the ORL, the algorithm was designed to particularly target the region bounded by the internal limiting membrane (ILM) and RPE layers. The ILM was segmented by an edge detection method; and the RPE was identified by the maximum value of the optical attenuation coefficient (OAC) along depth[1]. Then a percentile intensity-based threshold approach was developed to localize the upper/lower OPL boundary. The ORL thickness was then measured from the identified upper OPL boundary to RPE. Mean pixel-wise variation was assessed by comparing the upper boundary of OPL to the manual segmentation by expert graders.

Results: A total of 36 SS-OCT scans from 17 normal eyes and 2 eyes with geographic atrophy (GA) were included in this study. Auto-segmentation results were compared to manual segmentations in B-scans (Fig. 1). In addition to normal cases, the algorithm also achieved successful segmentation on GA cases (Fig. 1D-F). The mean pixel-wise difference between the algorithm and manual segmentation is 0.924 on normal cases, and is 0.38 on GA cases, demonstrating sufficient consistency and accuracy of the developed algorithm. The actual auto-segmentation could be better as the manual segmentation may be prone to errors when manually identifying the upper boundary of the OPL. In GA cases, the variation is smaller due to the limited sample size.

Conclusions: An automated ORL segmentation algorithm is developed for OCT scans, with demonstrated good stability and flexibility in normal and diseased eyes. The algorithm should be clinically useful in the investigations of possible ORL involvement in the AMD development.

ABSTRACT BODY:

Purpose: To develop a commercial-ready scanning laser ophthalmoscope system, the Retitrack, for retinal eye-tracking that can be used to quantify fixational eye motion and voluntary saccade characteristics.

Methods: A manufacturable confocal, lens-based SLO system, was created to record and analyze fixational and saccadic eye responses to a visual stimulus.

The Retitrack has a Head Unit, a Base Unit, and a Head & Chin Rest (Figure 1). The Head Unit is an illumination collection system for the capture of retinal images with eye motion output. A subject's retina is raster scanned, pixel by pixel, with a 5-degree field of view (FOV) containing 640x480 pixels using a 15 kHz resonance scanner and a 30 Hz galvanometer for the x and y-axis, respectively. A focusing lens is used to focus light onto a confocal pinhole and onto an Avalanche Photodiode (APD).

The Base Unit has an FPGA for syncing the timing of the scanners, sampling the APD output, and relaying it to a Nvidia Jetson Nano serving as the computer. Two motorized stages allow the optical scan path and optical fixation path to compensate for refractive error and are driven by the Jetson Nano based on the refractive error spherical equivalent through the software UI.

Results: The commercially viable device has software that records eye motion in standard mode (5-degree FOV) and montage mode (14.5-degree FOV) for fixational stability and visually guided saccades:

a) Fixational stability, including microsaccade and drift characteristics, are quantified and displayed. This can be recorded and analyzed in either Standard or Montage mode, using a stationary cross hair for visual stimuli for 10-second trials.

b) Visually guided saccades up to 7-degree in extent can be recorded and analyzed with Montage mode. Horizontal and vertical saccades are quantified with the presentation of two crosshair targets 5° apart.

Conclusions: The Retitrack device uses a scanning laser ophthalmoscope (SLO) to record, view, measure, and analyze the temporal characteristics of fixation and saccadic responses when viewing a visual stimulus. The detected light is used to generate a digital image with a computer which incorporates real-time, strip-based eye tracking methodologies to measure and report fixation and saccadic responses.

ABSTRACT BODY:

Purpose: Angiopoietin-Tie2/TEK signaling at the Schlemm's canal (SC) critically regulates aqueous humor outflow (AHO) and intraocular pressure (IOP) in humans and mice. Tie2 receptor loss-of-function mutations associate with primary congenital and open angle glaucoma (POAG), and conditional Tie2 knockout adult mice show SC regression, chronic IOP elevation and glaucomatous degeneration. However, systemic Tie2 deletion reduces choriocapillary flow, causing cone photoreceptor loss. To avoid potential effects on retinal/choroidal or systemic endothelial Tie2, we developed a targeted approach to selectively attenuate Tie2 expression in the SC of adult mice, and report their glaucomatous pathology.

Methods: Adeno-associated virus AAV2, which transduces rodent SC, was used to deliver Cre recombinase (AAV2-Cre) by bi- or unilateral injection into the anterior chamber of Tie2 $^{FL/FL}$ C57BL/6 mice aged 1-1.5 months. Live, we measured in AAV2-Cre vs. AAV2-GFP and naive littermates: weekly IOP (n>20 eyes/group) for 8 to 12 weeks post-injection (wpi), AHO facility 4 wpi (n=6-11 eyes), optomotor reflex and pSTR (n=5-13 mice), and retina/optic nerve head integrity by optic coherence tomography (OCT; n=7 mice) 12 wpi. Postmortem, we analyzed: AAV2 transduction 2-8 wpi (n=3-5 mice), and density of optic nerve axons and retinal ganglion cells immunostained for RBPMS and Brn3a 12 wpi (n=6-13 mice).

Results: AAV2-Cre selectively transduced the SC endothelium, leading to impaired AHO facility 4 wpi, and to significant IOP elevation from 1-4 wpi that persisted to 8 or 12 wpi. Visual acuity and pSTR amplitude were significantly decreased in AAV2-Cre eyes 12 wpi, relative to the controls, whereas ERG a- and b-waves were unaffected. OCT showed intact outer retinal layers, but significant thinning of the inner retina and optic nerve head 12 wpi. RGC analysis showed significant RBPMS+ RGC loss with maximal degeneration localized to the dorsal retina, and significant RGC decline (Brn3a-) preceding loss 12 wpi. Optic nerve analysis detected significant axon density drop, coupled to RGC loss, 12 wpi.

Conclusions: The "SC-Tie2 knockdown" model reproduces a pathogenic mechanism of humans POAG, undergoing chronic ocular hypertension, and progressive glaucomatous optic neuropathy and retinopathy. This model thus offers a robust and reproducible model of POAG, valuable for advancing its treatment.

ABSTRACT BODY:

Purpose: Late-onset retinal degeneration (L-ORD) is a rare autosomal dominant macular dystrophy caused by mutations in C1QTNF5. Microperimetry changes have been reported previously in L-ORD. The aim of this study is to validate microperimetry as a platform for longitudinal follow up in L-ORD.

Methods: This is a cross sectional clinical study with a subset of cases providing 4-year follow-up data. Patients were enrolled as part of a prospective study at the Princess Alexandra Eye Pavilion, Edinburgh, and the Royal Victoria Infirmary, in Newcastle. Patients were included in this analysis if they had foveal sparing dystrophy. Patients who were unable to do microperimetry were excluded.

Mesopic microperimetry was performed with a Nidek MP-1 microperimeter (NAVIS Software version 1.7.0) (Nidek Technologies, Italy). Following dilation, patients were dark adapted for 10 minutes and tested in 90 test locations using a Goldman size III white stimulus, in a customized test pattern covering the central 40 degrees. Stimulus duration was 200 milliseconds on a white monochromatic background ($1.27cd/m^2$) using a red fixation target and a 4-2 test strategy. The sensitivity of each test location was determined on a scale of 0 dB to 20 dB. The mean sensitivity was measured by taking an average of each location measured in each eye.

Results: A total of 20 eyes from 10 patients had baseline data (58.0 years +/- 4.77, 7 male). A subset of 10 eyes from 5 patients had follow up data. The mean baseline sensitivity was 10.02 dB (+/-5.26). Age was moderately negatively correlated with microperimetric sensitivity (r= -0.663).

For the follow up cohort, baseline mean sensitivity was 7.32 dB (+/- 5.21) at baseline which decreased to 4.69 dB (+/- 4.83) after 4 years of follow up. This approximated to 0.66 dB loss per year. Paired t-test confirmed a significant decrease in mean sensitivity over four year follow up ($p = 0.0008$).

Mean sensitivity was symmetric and was highly correlated between eyes of patients ($r = 0.979$) with no significant difference ($p = 0.054$) between eyes.

Conclusions: Our study demonstrates that microperimetric mean sensitivity is negatively correlated with age in our cohort. Microperimetric findings are symmetric. In addition, 4 year follow up shows a significant reduction in mean sensitivity suggesting that it is likely a useful tool for macular function follow up.

TITLE: Prediction accuracy of IOL power calculation in patients with a large difference between conventional keratometry and total keratometry

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hyon, Y. Son, Seoul National University Bundang Hospital, Seongnam, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Joon-Young Hyon: Commercial Relationship: Code N (No Commercial Relationship) | Yengwoo Son: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: With the advancement of technology, not only conventional keratometry (K) but also total keratometry (TK) can be measured. In previous papers comparing K and TK, no studies were showing statistical significance when comparing the two. This is because in general, there is no statistically significant difference between the two values. The purpose of this research is to investigate the IOL calculation in the cases where there are large differences between K and TK.

Methods: Study design: retrospective case series

Medical records of 15711 patients (37601 exams) who underwent IOL master 700 optical biometry were reviewed. Of the total, 825 patients (1835 exams) who had previously undergone refractive surgery were excluded. The number of patients with a difference of 0.5 diopter (D) or more in K-TK values was 77 patients (80 eyes), of which 14 patients (14 eyes) were subjected to IOL implantation. A study was conducted on 9 patients (9 eyes) excluding 5 cases undergone scleral fixation.

Results: All 9 patients had underlying diseases, two with a history of DSAEK, two with high myopia, two with corneal opacity, a bullous keratopathy, a Mooren’s ulcer, a history of epikeratophakia, and a pterygium. When using the algorithmic formula selection considering keratometry, anterior chamber depth, and axial length, the absolute prediction errors in K and TK groups were 0.663 ± 0.511 D and 0.349 ± 0.344 D (p-value=0.09). In the two groups, the prediction error within ±0.25 D was 1 eye (11%) and 5 eyes (56%), ±0.5 D was 5 eyes (56%) and 7 eyes (78%), and ±1.0 D was 9 eyes (100%) in both groups (within ±0.25 D vs the rest, p-value=0.102).

Conclusions: In cases of large differences between K and TK, IOL calculation based on TK showed better results.

ABSTRACT BODY:

Purpose: To investigate the relationship between topographical changes generated with orthokeratology and axial elongation using different orthokeratology lens platform.

Methods: This is a retrospective analysis using the data from the Montreal Experience study. Data were extracted from the file of each patient who consulted between January 2017 and December 2018 and were kept under the same myopia control strategy. The orthokeratology (OK) patients were selected (OK-4 designs, N=140) and corneal topographical analysis were done using the tangential differential maps between baseline and 3 months follow-up, which involved determining the treatment zone diameter (TZD) and the high mid-peripheral convex power. A comparison of the topographical corneal changes on the cornea was done between the four OK designs. Finally, the correlation was estimated between the relative area ratio between the convex zone and the distance zone in the subject pupil and the axial elongation after 1 year.

Results: There were no significant differences in the high peripheral convex power in all quadrant between the four OK designs.

Significant differences were found for the distance treatment zone diameter (DTZD) generated on the cornea between the OK L1 and the other designs, L2, L3 and L4. (horizontal = L1: 3.7 ± 0.45 mm ; L2: 3.00 ± 0.64 mm ; L3: 2.97 ± 0.58 mm; L4: 3.2 ± 0.58 mm).

The relative area ratio between the convex zone and the distance zone in the subject pupil showed a significative negative correlation with axial elongation after 1 year ($r = -0.48$).

Conclusions: In the Montreal orthokeratology patient cohort, it appears that the major difference created on the cornea between the four lenses used was the size of the treatment zone diameter, which appears to be related to the effectiveness in slowing axial elongation after 1 year when related to the subject's pupil. These results confirm the dose-response of the proportion of myopic defocus generative zone in orthokeratology on axial length management and reinforce the importance of analyzing topographic change in clinical and related studies of this method of myopia control.

ABSTRACT BODY:
Purpose: To study the temporal and spatial variability in OCT-Angiography measurement across the branching order of the vascular network and across instruments.
Methods: We measured 5 normal subjects a total of 10 times within a 30 minute session and recorded the OCT-Angiography scan according to the manufacturer's guidelines. We imaged the subjects in three difference instruments, the Heidelberg Engineering Spectralis OCT, the Optovue AngioVue and the Zeiss Cirrus 5000 Angioplex.
We used the build-in eye tracking feature for each instrument to align the follow-up exam of each scan with the first scan.
To analyze the data, we exported the OCT-Angiogram to ImageJ. In ImageJ we aligned the images to compensate for small variation in image alignment between repeat scans. We calculated the coefficient of variation (COV) for each blood vessel along the vessel tree.
Results: We found that the variability in OCT Angiography measurements is higher in smaller blood vessels and capillaries than in larger blood vessels. The variability was different between the three instruments.
Conclusions: This study compared the temporal and spatial variability in OCT Angiography measurements in normal subjects. The high temporal variability in smaller blood vessels indicates that the significance of OCT Angiography measurements based on a single measurement may be impacted. The reason for the high variability might be the snapshot approach of all OCT Angiography devices that capture only a fraction of the cardiac cycle in each vessel segment. Therefore, the natural variation in bloodflow may not be accurately sampled by a single OCT Angiogram.

ABSTRACT BODY:

Purpose: Choroidal neovascularization (CNV) is a leading cause of visual impairment and vision loss in humans. Therefore, it is important to establish an accurate, rapid, and durable animal model to perform CNV research. This study introduces a novel model involving laser induced CNV in pigmented rabbits in vivo. The model is longitudinally monitored using photoacoustic microscopy (PAM) and OCT to track development and maintenance of CNV.

Methods: CNV models were generated in 6 Dutch Belted Rabbits ages 2-4 months and weighing 1.9 to 3.0 kg. A laser contact lens was coated in Gonak Hypromellose Ophthalmic Demulcent Solution (2.5%) and placed directly on the eye. The eyes were then irradiated at a power of 450 mW with 532 nm laser light Vitra photocoadulator connected to a Zeiss SL 130 slit lamp. The rabbit eyes received 16 laser spots in a 4 x 3 rectangle with a spot size of 300 μm in aerial diameter and a pulse duration of 500 ms/spot. The models were monitored for 28 days, allowing time for CNV to generate and persist at the locations of laser irradiation. Longitudinal visualization of the models was acquired using multimodal PAM and OCT, fundus photography, FA, and ICGA. The rabbits were then euthanized, and histological analysis was performed to determine CNV or ocular damage.

Results: Using the multimodal imaging system, it was demonstrated that all 6 rabbit eyes had successful development and persistence of CNV in some of the laser irradiation sites. CNV developed approximately on day 14. This was deduced from leakage present on FA and ICGA images and 3D PAM and OCT data. In the FA images, the late leakage and hyperfluorescence observed was consistent with CNV. Histological analysis verified focal areas of laser damage. No rabbits had unexpected complications during the procedure or imaging.

Conclusions: The imaging data demonstrates that laser photocoagulation can effectively produce a stable model of CNV in pigmented rabbits. PAM and OCT imaging provide high resolution imaging of the growth of CNV without exogenous contrast agents. FA and ICGA confirmed the presence of CNV leakage.

TITLE: Comparing the efficacy between 0.09% cyclosporine, 0.05% cyclosporine, and 5% lifitegrast in patients with dry eye disease

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Kolluru, A. Nguyen, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Ajay Kolluru: Commercial Relationship: Code N (No Commercial Relationship) | Annie Nguyen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The prevalence of dry eye disease is estimated to be greater than 30 million adults in the United States. Three topical medications that are currently being prescribed in treatment of dry eye disease are 0.09% cyclosporine ophthalmic emulsion, 0.05% cyclosporine ophthalmic emulsion and 5% lifitegrast. The purpose of this study is to compare the efficacy of 0.09% cyclosporine, 0.05% cyclosporine and 5% lifitegrast by analyzing patient outcomes treated at an academic dry eye clinic, through a retrospective chart review.

Methods: Patients with dry eye disease treated with 0.09% cyclosporine, 0.05% cyclosporine or 5% lifitegrast and had a follow up of at least 3 months were included for analysis in this retrospective chart review. Variables included in the analysis were patient subjective improvement, Schirmer's test, tear osmolarity, and side effects of irritation and burning. A linear mixed-effects (LME) model, was used to study the relationship between treatment and each of the continuous or numeric outcomes of interest which included change in Schirmer test score, and change in tear osmolarity.

Results: A total of 40 patients were analyzed. There was not a significant association between the medication prescribed and 3-month follow-up subjective improvement in the sense of better, versus worse/same (n=28; Fisher exact test P=.820). For Schirmer test score (n=31) there was not a statistically significant association between the eye drop prescribed—0.09% cyclosporine, 0.05% cyclosporine, or 5% lifitegrast. (likelihood ratio test $\chi^2(2)=5.40$; P=.067) There was not a statistically significant relationship overall between the particular eye drop prescribed and the effects of days on tear osmolarity (likelihood ratio test $\chi^2(2)=5.61$; P=.061). There was not a significant association between the medication prescribed and irritation/burning at 3-month follow-up (n=25; Fisher exact test P=.350).

Conclusions: Current topical therapy for dry eye disease includes 0.09% cyclosporine, 0.05% cyclosporine, and 5% lifitegrast. There was no significant difference in efficacy between the different medications in this study. However, further studies are needed given the limitation of the small sample size.

ABSTRACT BODY:

Purpose: To study the occurrence of neovascular glaucoma in patients with severe diabetic retinopathy who were treated solely with anti-VEGF therapy and their treatment afterwards

Methods: We reviewed the outcome of eyes with severe diabetic retinopathy who were treated with anti-VEGFs alone. The patients were in follow-up care for two years, undergoing monthly structural OCTs and biyearly color fundus photography and fluorescein angiography

Results: Forty-five eyes from seventy patients who were treated with anti-VEGFs alone were followed for two years. Seven of these eyes developed neovascular glaucoma over the two-year follow-up. Two of the seven eyes had been treated with ranibizumab; two with bevacizumab; and three with aflibercept

All eyes with neovascular glaucoma were then treated with both panretinal photocoagulation and additional injections of the same anti-VEGF that was initially used. The neovascular glaucoma progression stabilized then. The presenting visual acuity varied between 20/100 to 20/400 prior to the treatment. All patients had worse acuity after treatment (20/400 to count fingers).

Conclusions: Neovascular glaucoma developed in eyes with diabetic retinopathy who are treated with anti VEGFs alone despite close follow-up. The condition responds well to treatment with panretinal ablation and additional anti VEGF injections, but despite the rigorous treatment, the visual outcome is poor

ABSTRACT BODY:

Purpose: To determine the most common treatment provided to patients with strabismus post plaque brachytherapy for choroidal melanoma. Secondary aims include determination of incidence and type of strabismus post plaque brachytherapy, and extraocular muscle most commonly removed and repositioned for plaque placement.

Methods: This study involved patients diagnosed with choroidal melanomas between October 2011-2020. Demographic data collected included patient age, gender and city. Outcome data included presence of strabismus post-plaque brachytherapy, strabismus treatment received, pre-and-post-operative visual acuity, tumour dimensions, tumour distance from the optic nerve and fovea, duration of follow-up post-plaque surgery, extraocular muscles operated, and primary deviation following treatment. Patients that developed strabismus post surgery underwent strabismus classification into slipped muscle, sensory, decompensated phorias, cranial nerve palsies, restrictive or a combination of the above.

Results: A total of 440 patients underwent plaque brachytherapy. 10/440 (2.27%) patients with treated choroidal melanoma developed strabismus. 7/440 (1.59%) patients were classified as having sensory strabismus, 2/440 (0.45%) slipped muscle, and 1/440 (0.22%) decompensating phoria. Of the 10 patients that developed strabismus, 1/10 (10.00%) is performing convergence insufficiency exercises, 2/10 (20.00%) require Fresnel for diplopia and are considering prism incorporation, 2/10 (20.00%) are awaiting consultation for strabismus surgery, 5/10 (50.00%) underwent strabismus surgery. Four of these patients had sensory exotropia and underwent lateral rectus recessions (1 had Botox prior to surgery). One patient had a combination of sensory exotropia and slipped muscle. Treatment for this patient included exploration and reattachment of the inferior rectus, superior rectus recession and Botox to the lateral rectus. A total of 389 muscles were removed and repositioned for plaque placement. The lateral rectus was the most common (157/389;40.36%), correlating to intraocular tumour location.

Conclusions: The incidence of strabismus post plaque brachytherapy was 2.27% over 10 years. Strabismus surgery was the most common treatment modality, comprising 50% of treatment for strabismus patients. Sensory strabismus was the most common, occurring in 1.59% of patients. The lateral rectus was the most common muscle repositioned during surgery, comprising 40.36% of all muscles repositioned.

TITLE: Inflammation modulates regeneration following acute or chronic retinal damage in zebrafish

SESSION TITLE: Neuron/Glia Interactions in Retinal Health and Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Iribarne, D. Hyde, University of Notre Dame, Notre Dame, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Maria Iribarne: Commercial Relationship: Code N (No Commercial Relationship) | David Hyde: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Unlike mammals, zebrafish regenerate in response to retinal damage. Because microglia are activated by retinal damage, we investigated their role during regeneration following acute or chronic damage. How inflammation regulates regeneration in zebrafish would provide important clues towards improving the therapeutic strategies for repairing injured mammalian tissues.

Methods: We used three weeks-post-fertilization (wpf) zebrafish exhibiting either NMDA-induced acute retinal damage or chronic retinal damage due to the cone photoreceptor-specific degeneration mutation gold rush (gosh). Fishes were treated with either dexamethasone to inhibit the immune response or LPS to stimulate the immune response. Immunohistochemistry and transgenic lines were used to monitor the proliferative response and microglia. Pro-inflammatory and anti-inflammatory cytokines were tested by qRT-PCR.

Results: NMDA-induced acute damage or the gosh chronic degeneration mutant displayed reactive microglia and Muuller glia proliferation. Retinas treated to inhibit the immune response lacked reactive microglia and possessed fewer PCNA-positive cells, while LPS treatment increased microglia and PCNA-labeled cells. NMDA-injured retinas upregulated the expression of IL-1β and TNF-α pro-inflammatory cytokine genes, followed by increased expression of IL-10 and Arg1 anti-inflammatory/remodeling cytokine genes. An early and transient TNF-α pro-inflammatory microglia population was identified following acute damage. In contrast, gosh mutant retinas exhibited a mild increase of pro-inflammatory cytokine gene expression concurrent with a major anti-inflammatory/remodeling cytokine gene expression. Few TNF-α pro-inflammatory microglia were observed in the gosh retina.

Conclusions: Acute or chronic retinal damage induces an immune response that modulates the proliferative response in zebrafish larvae. However, acute and chronic damage display different immunological response strategies. While acute damage presents an early and transient proinflammatory response, chronic damage presents a weak pro-inflammatory and a strong anti-inflammatory response simultaneously.

TITLE: Impact of Unequal Contrast on the Range of Disparity Sensitivity (Dmin & Dmax)

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Lew, D.R. Coates, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Wei Hau Lew: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Coates: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In a real-world scenario, disparity sensitivity depends on both the smallest stereo threshold (Dmin) and its upper limit to double vision (Dmax). Studies have shown that Dmin reduces with lower contrast and blur, more strongly in the monocular than in the binocular conditions. However, little is known about the effect of Dmax across different spatial frequencies in a complex task, especially with unequal image properties between the two eyes, such as contrast differences. Here, we assess the effect of contrast on the range of disparity sensitivity function (DSF) in a stereo letter recognition task.

Methods: Previously, we developed a stereo test consists of Sloan letters with crossed disparity embedded in Random dot stereograms, viewed through active-shutter goggles and a 3D monitor. A letter, corresponding to 0.5-2cpd at 10ft, appeared in front of the background RDS (1sec) at different depth planes, and subjects identified the letter seen. Adaptive staircases were used to obtain Dmin and Dmax. Uncorrelated background RDS were used to measure Dmax. With correct responses, the letters in the Dmax staircase are presented closer to the observer until fusion breaks, making the letters unrecognizable. The range of the DSF was determined as the difference between Dmax and Dmin. Three subjects performed the experiment, at high contrast, and with different contrast combinations (100, 32, and 10%) in monocular and binocular conditions. One eye's contrast was fixed at 100% in the monocular condition.

Results: With stereo letters varying in sizes, the Dmin and Dmax curves were lowpass in shape. The range of DSF was more extensive at low SF (~35 to ~4500 arcsec) and condensed at higher SF (~80 to ~1800 arcsec). With lower contrast, Dmin increased while Dmax reduced, resulting in a smaller DSF range (Kruskal-Wallis, p=0.005). Comparing between congruent and incongruent contrast conditions, the range was smaller across the SFs, but was statistically significant only at 10% contrast.

Conclusions: Our result illustrates the shrinkage of the range of functional stereopsis, especially under unequal contrast. With lower contrast, maintaining fusion is more challenging, the range of DSF is smaller, and the probability of seeing double is higher, more so in the unequal condition. One should consider both Dmin and Dmax when the image quality between the two eyes is unequal, such as in the case of monovision or contrast differences.

ABSTRACT BODY:

Purpose: While some data about the ophthalmology fellowship match has been reported, studies investigating the details and trends in retina fellowship positions are lacking. Therefore, we performed a retrospective study of the San Francisco Match Central Application Service (CAS) database to identify program characteristics and trends for retina fellowships.

Methods: The CAS database was reviewed from 2010 to 2019. The total number of retina fellowship positions were recorded and classified by location, association with an ophthalmology residency, as medical-only or medical/surgical retina, and compliance status set by the Association of University Professors of Ophthalmology - Fellowship Compliance Committee (AUPO-FCC). Programs that did not provide sufficient information to make the above classifications were excluded.

Results: The number of retina fellowship positions offered annually increased 57% (102 to 160) from 2010 to 2019; medical retina-only and medical/surgical fellowship programs increased 257% (7 to 25) and 40% (67 to 94), respectively. In 2019, 59% (95 of 160) of positions offered were compliant with AUPO-FCC standards and 71% (114 of 160) of positions offered were associated with an ophthalmology residency. The state with the greatest number of fellowship positions in 2019 was California (20) and 20 states did not offer any positions. Of the 37 vacant positions in 2019, 78% (29) were not certified by the AUPO-FCC.

Conclusions: The number of retina fellowship positions offered has grown over the last decade. With the increasing prevalence of retinal diseases, further study is needed to determine if the increase in workforce will be commensurate with future needs.

ABSTRACT BODY:

Purpose: Histiocytic-dendritic (HD) neoplasms may involve the eye and other organs resulting in significant morbidity and even mortality. Previous studies of non-periocular HD demonstrated mutations in mitogen-activated protein kinase (MAPK) genes leading to MAPK pathway activation. As a result of MAPK signaling activation, expression of CCND1 (cyclin D1) protein is upregulated. CCND1 immunohistochemical (IHC) stain has been shown to be a useful ancillary diagnostic marker and to correlate with MAPK gene mutations in non-periocular HD neoplasms. Our objective was to determine whether periocular HD neoplasms express CCND1 via IHC and to further characterize their genetic basis.

Methods: We retrospectively searched pathology records for all patients with HD neoplasms diagnosed (years 1995-2020). Select cases with non-specific histiocyte-rich ocular adnexal inflammation served as controls. Immunohistochemistry was performed with CD68, S100, CD1a, and CCND1. A subset of HD Neoplasms was evaluated via next generation sequencing (NGS) and digital droplet PCR (ddPCR).

Results: HD neoplasms were identified in 36 patients: juvenile xanthogranuloma (N=9), adult onset asthma and periocular xanthogranuloma (N=8), Langerhans cell histiocytosis (N=7), Rosai-Dorfman disease (N=5), adult isolated xanthogranuloma (N=5), Erdheim-Chester disease (N=1), and histiocytic sarcoma (N=1). Eleven patients with non-specific histiocyte-rich inflammation were selected as controls. Compared to non-specific inflammation, HD neoplasms demonstrated strong nuclear staining for CCND1 in >50% lesional cells [23/36 (64%) vs. 0/11 (0%), $p<0.001$]. NGS and ddPCR on a subset of 17 histiocytic-dendritic neoplasms demonstrated MAPK gene mutations in all 16 cases with amplifiable DNA.

Conclusions: CCND1 immunohistochemistry is a useful diagnostic marker for periocular HD neoplasms, correlating with underlying mutations in MAPK genes.

ABSTRACT BODY:

Purpose: To develop and produce a non-toxic protein therapeutic for the repair and regeneration of the retinal vasculature in eyes affected by ischemic retinopathies, by targeting and stimulating endogenous retinal endothelial cells. A strategy for producing Noregen protein in bacteria, based on the human norrin protein, was developed and tested for toxicity, in vitro activity and in vivo efficacy.

Methods: A method was refined to produce Noregen (human-derived growth factor) protein as inclusion bodies in E. Coli, to meet several milestones. 1) Culturing at least 1,000 mg per Liter of protein. 2) Purifying protein sufficiently for safe intravitreal injection in the rat eye as confirmed by ERG. 3) Refolding Noregen to produce active protein. Activity was measured by a receptor (Frizzled-4) binding assay, RT-PCR to determine alterations in Norrin-target gene expression (AXIN-2 & PLVAP) in primary human retinal endothelial cells and use of a mouse OIR model to evaluate accelerated vascular regrowth in vivo. OIR mice (n=11) were removed from 75% oxygen at post-natal day (P) 12 and received a single injection of either Noregen 40 ng (n=6) or Vehicle (n=5) in the left eye at P14. Eyes were evaluated by retina whole mount and lectin staining at P17.

Results: Production of protein met and then exceeded the desired culture concentrations. Noregen protein was refolded into a biologically active state and achieved sufficient binding to Frizzled-4, matching the binding EC50 of Norrin (30-150 ng/mL). Purification was reached to minimize endotoxin and no toxicity was detected in the Long Evans rat eye based upon analysis with fluorescein angiography, Spectral Domain-Optical Coherence Tomography (SD-OCT), and full-field electroretinogram (ERG) up to 6 weeks following a single intravitreal injection of Noregen 250 ng. Significant vascular regrowth was seen in the Noregen treated eyes compared to vehicle treated eyes (p=0.027). Noregen treatment of primary HRMECs increased AXIN-2 gene expression (Wnt pathway activation) similar to human norrin, increased cell proliferation in a dose dependent fashion, and suppressed PLVAP (marker of transcytosis).

Conclusions: Noregen, a novel protein therapeutic, was successfully produced in E. Coli at sufficient scale, purity and biological activity to enable the continued development of Noregen for future GMP grade manufacturing.

ABSTRACT BODY:

Purpose: In vitro culture systems generally apply homogeneous stimuli and rely on intercellular signaling to guide growth of tissues. However, to derive complex tissue structures such as the human retina, a gradation of certain stimuli is required. The inner retina resides in a hypoxic environment (2% O_2) adjacent to the vitreous cavity. From there, oxygenation levels rapidly increase towards the outer retina (18% O_2) at the choroid. Here we developed a novel tissue bioreactor allowing the maturation of inner and outer retinal cell phenotypes within an O_2 gradient.

Methods: The bioreactor is assembled from a 75x25x3 mm acrylic slide, a PFA film, a cover glass, and double-sided adhesives, which were adjusted with computer numerical control milling and laser cutting (Fig. 1A). The 60 culture wells of 2 mm in diameter and 0.7 mm high each hold one retinal organoid. A nitrogen (N_2) tank provides the bioreactor with 5 mL/min N_2 gas and a dual syringe pump creates a 5 µL/min continuous flow of culture medium though the bioreactor (Fig. 1B). Gas diffusion through the PFA membrane and culture medium was predicted using computational modeling software for atmosphere (20.9% O_2) and incubator (18.6% O_2) conditions. O_2 concentration measurements were performed with O_2 sensors along the z-axis in 50 µm steps in atmospheric conditions.

Results: The gas diffusion throughout the culture medium resulted in an O_2 concentration gradient along the z-axis (Fig 1C). The computational predictions in atmospheric conditions are in accordance with the measurements around the retinal organoid location in the bioreactor (Fig. 1D).

Conclusions: This open-well bioreactor is easily accessible for downstream analysis, establishes a steep O_2 gradient and allows high-throughput retinal organoid culture. It will help retinal organoids mature into the complex structure to use them for disease modeling and drug testing.

ABSTRACT BODY:
Purpose: Intracortical visual prostheses (ICVPs) generate a phosphene map in wearers' visual fields. Three modalities, finger pointing, eye movement, and head movement, are tested for reconstructing ICVP patients' phosphene map, but each may have considerable distortion. The distortion may be reduced by scaling the simulated phosphene map obtained from each of the above modalities.
Methods: Normally sighted participants were shown a set of 32 dots ("phosphenes") in the central 35° of the lower-left visual field quadrant, one by one, in a VIVE Pro Eye headset. Participants indicated the location of the phosphene by finger-pointing, eye movement, and head movement. Finger positions were collected in two conditions: finger-eye and finger-head. Each condition was repeated three times. Polhemus G4 trackers recorded finger positions and head movements. Eye movements were recorded using the VIVE Pro Eye built-in tracking feature. Data analysis was performed through shifting and scaling the clusters of obtained dots to equate their centers of mass and dispersions to those of the original phosphenes.
Results: Across all obtained data, the average scaling factor for eye maps, finger maps, and head maps are 0.75(±0.18), 0.41(±0.11), and 0.60(±0.17), respectively. The average distances between scaled dots and original phosphenes in eye, finger, and head maps were 1.56°, 1.71°, and 2.53°, respectively. Thus, similar scaling factors were observed across subjects for all three settings; eye position and finger movement had better accuracy and precision than head movement.
Conclusions: Since the three scaling factors are similar across sighted subjects, we can apply these factors to blind subjects' data. Furthermore, the scaled phosphenes were close to the original ones, so we can expect the scaled phosphenes to be sufficiently accurate for image presentation in blind subjects.

ABSTRACT BODY:

Purpose: The alternate complement pathway and age-related macular degeneration (AMD) have been long connected via genetic association studies. The complement factor H (CFH) gene has one of the highest odds ratio for the disease propensity, and dysregulated alternate complement pathway is thought to accelerate the disease phenotype. RPE cells with the highest CFH expression are the likely initiation site for complement attack. Using iPSC-RPE derived from patients with risk(Y402H) and non-risk(H402H) CFH alleles, we aim to decipher the role of CFH in disease propensity under a complement attack and determine genotype to phenotype interaction.

Methods: Four iPSC lines from CFH risk Y402H and three from non-risk H402H variants were differentiated into RPE and confirmed for functionality and maturity. To check if CFH risk-allele containing iPSC-RPE show signs of vulnerability to complement attack, we tested secreted CFH, C3a, and C5a levels, phagocytic ability, monolayer transepithelial resistance (TER) with and without complement serum. In addition, cells were stained with sub-RPE deposit marker-APOE, lipid droplets with Nile red, and BODIPY and complement lytic attack complex to check the AMD phenotype.

Results: CFH risk variant iPSC-RPE showed lower outer segment digestion capacity, and lower TER. CFH high-risk cells also had significantly higher sub-RPE and lipid deposits than CFH non-risk variant iPSC-RPE, suggesting disease vulnerability. The lower CFH secretion and higher C3a and C5a levels in CFH risk variants likely is the downstream mechanism making these RPE cells susceptible to AMD.

Conclusions: iPSC-RPE from the CFH risk variant recapitulated the AMD phenotype at basal levels and under complement attack- creating AMD model in a dish. This study provides a tool to decipher genotype interaction with macular degeneration phenotype and other retinal dystrophies. In addition, this platform can be used to further study interactions between different risk alleles such as ARMS2/HTRA1 and to perform drug screens to discover potential therapeutic agents.

ABSTRACT BODY:

Purpose: Retinal vein occlusions (RVOs) are the second leading cause of vascular blindness, where anti-VEGF agents are among the first-line treatment options. Recent developments in artificial intelligence (AI) models have shown promise in OCT fluid segmentation and predictive value in anti-VEGF treatment outcomes. However, there are currently no trials demonstrating AI with swept-source Optical Coherence Tomography (SS-OCT) images in concordance with OCT analysis for RVO patients.

Methods: 49 treatment-naive subject eyes were diagnosed with visual impairment due to RVOs, either central (CRVO) or branch (BRVO). SS-OCT data was used to assess retinal layer thicknesses, as well as quantify intraretinal fluid (IRF), subretinal fluid (SRF), and serous pigment epithelium detachments (PEDs) using a deep learning-based, macular fluid segmentation algorithm. Patients received 3 loading doses of 2 mg intravitreal aflibercept injections (IAI). Image analysis was performed at baseline, month 3 & month 6 follow-up. Baseline OCT morphological features and fluid measurements were correlated using the Pearson correlation coefficient (PCC) to changes in BCVA to determine which features most impacted 6-month change in BCVA. The difference between areas of non-perfusion in OCT-A images treated with and without a denoising algorithm would also be evaluated.

Results: A combined model of thickness in the Outer-Plexiform Layer (OPL), retinal nerve fiber layer (RNFL) and presence of IRF had the strongest overall correlation for CRVO (PCC=0.865, $p < 0.05$); while for BRVO the addition of IRF to the OPL-Inner Nasal model had a strong correlation (PCC=0.803, $p<0.05$). Baseline Ischemic Index in the Deep Capillary Complex (DCP) for CRVO without denoising demonstrated notable correlation with 6-month change in BCVA (PCC=0.7501, $p = 0.079$), and denoising strengthened this correlation (PCC=0.9100, $p = 0.0101$).

Conclusions: A combined model of IRF and thickness, alongside ischemic indices provide the best correlation to BCVA changes. This is clinically consistent given that the DCP supplies the OPL, as macular fluid builds up, these vessels have reduced flexibility to accommodate; thus becoming more occluded, causing further damage to the OPL. Ultimately, an AI approach to analyzing fluid metrics may provide an advantage in personalizing therapy and predicting BCVA outcomes for RVO patients.

ABSTRACT BODY:

Purpose: Scleral buckling (SB) can be used alone or in combination with pars plana vitrectomy (PPV) for the treatment of rhegmatogenous retinal detachment (RRD). In specific cases, buckle removal is necessary due to SB-related complications. The purpose of this study is to investigate the indications of SB removal and the rate of recurrent retinal detachment in these patients.

Methods: This was a retrospective cohort study. The medical records of eyes operated for RRD with SB (simple SB or in combination with PPV) at CHU de Québec – Université Laval (Quebec City) between 2008 and 2020 were reviewed. Exclusion criteria included non-RRD of tractional or traumatic etiology. The indications for all cases of SB removal were reviewed. The primary outcome of interest was recurrence of retinal detachment following SB removal.

Results: Out of 2375 eyes that underwent SB for treatment of RRD, 40 eyes had SB removal (1.7%). The main indication for SB removal was infection, occurring in almost a third of patients (n=13, 32.5%). Pain/intolerance (n=12, 30%), buckle extrusion (n=6, 15%), strabismus and/or diplopia (n=3, 7.5%) and other causes including persistent inflammation and increased intraocular pressure (n=6, 15%) made up the remaining indications. The median time from scleral buckle placement to removal was 11.5 months, but in 25 cases (62.5%), the buckles were removed after less than 6 months, and an additional 37.5% (n=15) of cases after more than 1 year. Patients who had infection as the primary cause of SB removal were likely to have earlier removal of SB (median [Q1, Q3] in months) than those with SB removal for other reasons (infection: 2.8 [1.1, 9.5] vs. other causes: 11.2 [6.3, 25.1]; p=0.012).

After SB removal, recurrent retinal detachment was observed in 7.5% of eyes (n=3), with all recurrences occurring within the first month. All patients underwent PPV without placement of a SB. Re-detachment occurred in all three patients within the first 6 months.

Conclusions: The indications for SB removal are numerous, with infection making up one third of cases and generally necessitating earlier intervention. There is a 7.5% risk of redetachment after SB removal. Additionally, treatment of recurrent RRD post-SB removal is associated with a high rate of failure and should therefore be carefully considered.

TITLE: Role of Hyperinsulinemia and Hyperglycemia in Outer Blood Retinal Barrier (BRB) Breakdown

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Hernandez, Pharmacology, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|K. Hernandez, L. Pollock, B. Anand-Apte, Ophthalmology, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Karen Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Lana Pollock: Commercial Relationship: Code N (No Commercial Relationship) | Bela Anand-Apte: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of preventable blindness in developed countries. Breakdown of the blood retinal barrier (BRB) leads to macular edema and is one of the earliest events in the development of DR. Previous work from our laboratory suggest that hyperinsulinemia (as seen in type 2 diabetes) may lead to disruption of the outer BRB. The purpose of this study is to explore the effect of hyperglycemia/hyperinsulinemia on the permeability and expression of tight junction proteins (claudin 19, claudin 10, zonula occludens-1 (ZO-1) in primary porcine retinal pigment epithelial (RPE) cells. The proposed study will provide a better understanding of the molecular mechanisms involved in the breakdown of the BRB in DR.

Methods: Impedance spectroscopy was used to evaluate the transepithelial electrical resistance (TEER) as well as capacitance of primary porcine RPE cells grown in media containing 5 mM D-glucose (mimicking physiological conditions) or 25 mM D-glucose (mimicking high glucose as seen in diabetic patients). Once cells reached confluence, the effect of exposure to 100 nM insulin over 2 weeks was evaluated. Expression of tight junction proteins were evaluated by western blotting and the spatial localization of these proteins was evaluated by immunofluorescence.

Results: RPE cells cultured in physiological glucose (5mM) had a lower TEER compared to RPE cells cultured in high glucose (25mM). Insulin induced a significant decrease in TEER in RPE cells only in high glucose (25mM) conditions with no effect on cells cultured in physiological glucose media.

Conclusions: These data suggests that high levels of insulin can induce BRB breakdown under hyperglycemic conditions and may have implications for the development of DR in type 2 diabetes.

ABSTRACT BODY:

Purpose: Individuals with mild traumatic brain injury (mTBI) exhibit significant accommodative abnormalities that can impair their near-work comfort and efficiency. Accommodative insufficiency is widely reported in mTBI patients who show significantly higher accommodative error (AE). Accommodation microfluctuation (AMF) plays an important role in the accommodation steady-state control mechanism. The purpose of this study was to investigate the impact of mTBI on the characteristics of the AMF.

Methods: Monocular static accommodation was recorded continuously for 1 minute from 54 healthy (age 21-30 years) and 30 mTBI subjects (age 18-33 years) using Power Refractor 3 at 5 accommodative stimulus (AS) levels (0 to 5 D). The accommodative response (AR) data were processed using Fast Fourier Transform to determine the amplitude of high (HFC), medium (MFC), and low (LFC) frequency components of the AMF.

Results: Consistent with previous reports, the amplitude of LFC increased as the AS increased in both groups (Fig 1a). However, mTBI subjects showed a significantly lower LFC amplitude than that of the control at higher AS levels (3 D – 5 D) (main effect $F_{(1,78.7)} = 8.56$ ($p < 0.01$). Similar group effect was also observed for the HFC ($F_{(1,77.9)} = 5$ ($p = 0.028$) (Fig 1b). Pairwise comparison revealed that the HFC amplitude was significantly lower in the mTBI than the control group for 2D, 3D, and 4D stimulus levels. There was no significant difference between groups for the amplitude of the MFC. Interestingly, a strong correlation between the AE and the LFC of AMF was revealed for all AS levels (except 0D) in both groups (Fig 2). Lead of accommodation (AE< 0) was associated with higher LFC amplitude, and lag of accommodation (AE > 0) was associated with lower LFC amplitude. No correlation between the AE and MFC or HFC was observed.

Conclusions: Our data is the first to show impairment of AMF in subjects with mTBI. Both the LFC and HFC showed significantly lower AMF amplitude compared to the control group. The magnitude of LFC was correlated with AE in both groups, suggesting that AMF may be influenced primarily by the changes in the motor output properties of the accommodation plant with increasing accommodation response.

TITLE: Modelling and measuring the viscoelastic properties of the in vivo rat eye

SESSION TITLE: Aqueous humor dynamics, IOP, corneal disease, cytokines and growth factors

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y.H. Mohamed, C.L. Passaglia, Medical Engineering, University of South Florida, Tampa, Florida, UNITED STATES|Y.H. Mohamed, USF Health Morsani College of Medicine, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure: Youssef Mohamed: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Passaglia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Goldmann Equation models the eye as a purely resistive element, which is adequate understeady-state conditions but insufficient to quantify the dynamic properties of the eye. We propose a model with both resistive and viscoelastic components that represent the trabecular meshwork and scleral shell, respectively. This study aims to use the model to measure viscoelastic parameters of rat eyes.

Methods: Figure 1 provides a schematic of the viscoelastic eye model and experimental setup, which was simulated in MATLAB. Two 33-gauge needles were advanced into the anterior chamber of anesthetized Brown-Norway rat eyes. The first needle was connected to a pressure transducer to record true intraocular pressure (IOP). The second needle was attached to a stopcock connected with 25-gauge tubing to anotherpressure transducer, a flow meter, and a controllable pump. IOP and flow data were collected at 50Hz. Outflow facility (1/RT) was measured by recording steady-state flow at multiple IOP setpoints. Ocular compliance (CW) was measured by recording IOP responses to bolus injections of varying volumes. To determine corneoscleral resistance (RW), the time constant of the eye was measured by fitting an exponential function to the decay in IOP after a pressure step. RW was calculated from the measured facility, compliance, and decay time as follows: t = CW (RW + RT). To help minimize error, a third needle of small and known resistance RSH was inserted in the eye as a shunt, eliminating uncertainties in RT.

Results: Viscoelastic data were successfully collected from 5 animals. Model simulations accurately described measured pressure and flow dynamics to step changes in IOP of 5 mmHg. $1/R_T$, C_W, and t were measured to be 0.017 ± 0.01 $ml*min^{-1}*mmHg^{-1}$, 0.08 ± 0.05 $ml*mmHg^{-1}$, and 0.18 ± 0.05 min, respectively. Based on these results, R_W averaged 2.22 ± 1.27 $mmHg*min*ul^{-1}$ across animals.

Conclusions: The viscoelastic model captures ocular fluid dynamics of anesthetized rats to pressure and flow steps. The “shunt method” provides a quick and accurate means of estimating Rw. RW is relatively small but may cause overestimation of RT if measurements have not reached steady state.

TITLE: Multiplex Immunofluorescent Demonstration of B-DNA, Z-DNA and G4-Quadruplex DNA in the Mouse Crystalline Lens: Spatial Genomic Organization of Different DNA Structures, i.e., Genomesorganizomics

SESSION TITLE: Lens Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Gagna, Biological and Chemical Sciences, New York Institute of Technology, Old Westbury, New York, UNITED STATES|

Commercial Relationships Disclosure: Claude Gagna: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The lens is an excellent system to investigate molecular biological processes, such as mitosis, cellular quiescence, stem cells, cellular differentiation, and cell death. Our group wanted to demonstrate, for the first time, the presence and distribution of three totally different types of DNA structures in the anterior epithelial cells and nucleated secondary fiber cells of the normal lens. DNA is a dynamic molecule and can adopt many structures, such as canonical right-handed double-stranded (ds-) B-DNA, left-handed ds-Z-DNA, and four-stranded G4-quadruplex DNA. These DNAs have different molecular biological functions in eukaryotic cells.

Methods: Twenty mice (Jax) were sacrificed and histotechnologically processed (Davidson's fixative) to obtain paraffin-embedded tissue section (3.0 μm). Using anti-DNA monoclonal antibodies (MAbs), (i.e., anti-ds-B-DNA, anti-ds-Z-DNA, and anti-G4-quadruplex DNA MAbs), we localized and quantified tissue-bound DNAs in the nucleus of epithelial cells, and nucleated secondary fiber cells undergoing cell death: terminal differentiation, i.e., denucleation. Immunofluorescence (IF) was performed using a confocal microscope and advanced computer analysis software. Cells were counterstained with wheat germ agglutinin. AR enhanced IF of certain DNAs. Both positive and negative controls were used.

Results: Our data shows that all three types of DNA can be identified within the nucleated cells of the epithelium [i.e., central zone, pre-equatorial zone, germinative zone, meridional rows, and differentiating cells], and nucleated secondary fiber cells. IF was highest in the GZ and lowest in the CZ. IF decreased at different rates within denucleating cells depending on type of DNA. No IF was observed in the annucleated secondary and primary fiber cells. AR enhanced IF of certain DNAs.

Conclusions: All three types of DNAs are regulating different roles in the molecular biology of genes and telomeres in the lens. We are applying a novel "omics" method towards the characterization of DNA structure found within the nucleus, i.e., "Spatial Genomic Organization of Different DNA Structures: Genomesorganizomics". Future research will demonstrate how DNA structures specifically influence the biology of lens cells managing proliferation, differentiation and cell death.

ABSTRACT BODY:

Purpose: As few methods exist to reliably quantify visual photosensitivity, the Ocular Photosensitivity Analyzer (OPA) was devised (Aguilar et al. BOE 2018, 9(11): 5583-5596). This study was conducted to assess the test-retest reproducibility of the OPA to quantify visual photosensitivity thresholds (VPT) in healthy subjects across two visits.

Methods: This IRB-approved study included 25 healthy adults with no history of ocular abnormality. During two in-person visits, subjects were administered study questionnaires (VLSQ-8: Visual Light Sensitivity Questionnaire-8, OSDI: Ocular Surface Disease Index, NPSI-E: Neuropathic Pain Symptom Inventory for the Eye) and filled out a medical history form. VPT was measured with the OPA, an automated device that assesses subjects' responses to multiple light stimuli presented at varying intensities. The test-retest reproducibility for VPT measured at each visit was analyzed by reliability analysis. An Intraclass Correlation Coefficient (ICC) ≥ 0.90 was considered to indicate excellent reliability. Correlation between VPT and study questionnaire responses were assessed via linear regression. An R^2 ≥ 0.7 was considered significant.

Results: The average age of the subjects (n=25) was 32.5±13.3 years, 48.0% self-identified as male, 64.0% as White, and 24.0% as Hispanic. Visit #1 and Visit #2 were conducted 34.1±7.1 days apart. The mean measured VPT in healthy subjects were 2.5±0.8 log lux at Visit #1 and 2.3±0.8 log lux at Visit #2. The test-retest reproducibility for healthy subjects measured during the two in-person visits had excellent reliability (ICC = 0.92). Overall, dry eye and ocular pain scores were low in our healthy population (VLSQ-8 11.3±3.5, OSDI 1.2±1.8, NPSI-E 0.8±1.6). No significant correlations were found between VPT and study questionnaire responses (R^2=0.03 – 0.06, p>0.05).

Conclusions: The data indicate that the OPA is a reliable tool for quantifying visual photosensitivity in individuals without ocular disease. Ongoing studies are being performed to increase our subject population and examine repeatability in subjects with TBI associated visual photosensitivity.

ABSTRACT BODY:

Purpose: North Carolina macular dystrophy (NCMD) is an autosomal dominant developmental disease, hypothesized to be a retinal enhanceropathy with noncoding variants and duplications overlapping with cis-regulatory elements (CREs) near PRDM13 or IRX1 as genetic cause. We aimed to provide insight into the disease by single-cell (sc) transcriptional dynamics and in vivo enhancer assays.

Methods: Single-nucleus RNA-seq (snRNA-seq) data of embryonic (53, 59, 74, 78, 113 & 132 days) and adult (n=3) human retina (PMID:34788628) was mined for sc expression of PRDM13 and IRX1. Expression matrices from these samples (GSE183684) were imported into R and processed using Seurat. Harmony was used to merge all sc data. Five previously identified candidate CREs (cCREs, 3 for PRDM13, 2 for IRX1) were assessed using enhancer assays in Xenopus (X.) tropicalis and/or albino X. laevis using a fluorescent enhancer detection vector and transgenesis via I-SceI meganuclease.

Results: SnRNA-seq data from all retinal samples was put into ten clusters representing the major retinal cell types. Transcriptional profiling during retinal development showed predominant expression of PRDM13 in amacrine cells, with low expression in retinal progenitor cells (RPCs), horizontal, and retinal ganglion cells (RGCs). IRX1 showed low expression during development, with highest expression in RGCs and weakest in RPCs. The first mutational hotspot of PRDM13 did not drive EGFP reporter expression in X. tadpoles (Nieuwkoop & Faber (NF) stage 42), while the second hotspot region drove EGFP expression in eye and brain. The first tested IRX1 cCRE drove EGFP expression in the neural plate and tube at NF stage 15 and 20. At NF stage 42 and 45 EGFP expression was seen in neural crest derivatives and the eyes, and at stage 55 reporter gene expression was maintained in the eye. The cCRE containing the shared duplicated region of IRX1 showed lower EGFP expression.

Conclusions: A shared developmental expression in amacrine cells and RGCs and to a lesser extent in RPCs has been shown for PRDM13 and IRX1. Genetic defects in both loci may affect CREs that are active in early RGCs. Due to the dominant nature of NCMD a gain-of-function impairing PRDM13 or IRX1 expression can be suspected, perturbing macula-specific synaptic interactions between amacrines and RGCs during retinogenesis.

TITLE: Intravitreal injection dead volume varies significantly with different forces applied to TB, ranibizumab, and aflibercept syringes

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.A. Lemire, E. Gonzalez, Department of Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|C.A. Lemire, E. Gonzalez, J.J. Raevis, Division of Ophthalmology, Beth Israel Deaconess Medical Center, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Colin Lemire: Commercial Relationship: Code N (No Commercial Relationship) | Efren Gonzalez: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Raevis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The optimal syringe to use for intravitreal injections remains under debate. We investigated the relationship between the force applied to the syringe and volume output.

Methods: Empty pre-filled syringes of aflibercept and ranibizumab as well as 1 mL tuberculin (TB) syringes, used for bevacizumab injections, were filled with 50 µL of deionized water. Syringes were attached to a 32-gauge needle and held in an apparatus with weights being placed in 50 g (0.49 N) increments until the plunger was completely depressed and fluid ceased exiting the needle. Following this equilibrium point, additional weight was added serially to increase the force on the plunger. The mass of water expelled at each force was measured and converted to volume (1 mg water = 1 µL water). Six trials of each syringe were performed, and differences were compared using an ANOVA test. Pairwise differences were calculated with t-tests.

Results: The mean total excess volume with 400 g (3.92 N) being added after equilibrium was reached was 8.58 µL for aflibercept (95% CI: 8.04-9.13), 5.70 µL for ranibizumab (5.13-6.27), and 0.40 µL for the TB syringe (0.14-0.66). One-way ANOVA revealed that the mean total excess output was significantly different between the three syringes ($F = 495.6$, $p = 2e\text{-}14$) and t-tests found significant differences between all syringe pairs ($p < 0.0001$).

Conclusions: Ideally, 50 µL is injected with intravitreal injections, but with only 400 g of extra weight applied to the depressed plunger the output volume increased by 17% from the aflibercept syringe and 11% from the ranibizumab syringe. Under the same conditions, the TB syringe expressed only 0.8% more volume. Design elements of the syringes, including the domed shape, compressibility of the stopper, short push length, and large diameter of the plunger likely account for the differences. Given the small volume of intravitreal injections, the effect of force on syringe output should be minimized to prevent improper dosing of medication.

TITLE: Posterior vitreous detachment increases macrophage-like cell density

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Wang, J.X. Ong, P.L. Nesper, A.A. Fawzi, J. Lavine, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Jacob Wang: Commercial Relationship: Code N (No Commercial Relationship) | Janice Ong: Commercial Relationship: Code N (No Commercial Relationship) | Peter Nesper: Commercial Relationship: Code N (No Commercial Relationship) | Amani Fawzi: Commercial Relationship(s);Code C (Consultant/Contractor):Boehringer Ingelheim, Regeneron, Genentech/Roche | Jeremy Lavine: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) imaging has identified mobile, ramified macrophage-like cells (MLCs) at the vitreoretinal interface in human subjects. The identity of MLCs remains unknown and a potential cell type includes vitreal hyalocytes. We performed OCT and OCT angiography (OCT-A) imaging in patients with and without posterior vitreous detachment (PVD) to determine if MLCs exist in the retina or vitreous, and to determine if PVD status changes MLC detection.

Methods: We imaged 21 eyes from 21 subjects, including 11 eyes with no PVD and 10 eyes with PVD. Repeated foveal-centered 3 x 3 mm OCT-A images were obtained (mean: 6.0 repeats, range: 4–10). The images were segmented, registered, and averaged. The OCT slab segmented from 0 to 3 microns above the internal limiting membrane was used to detect MLCs, which were binarized and quantified using our previously published semi-automated method. The distribution of MLCs in relation to vessels in the superficial capillary plexus was investigated, and MLC density was calculated for 3 vascular regions – on vessels, perivascular, and ischemic (>30 microns from the nearest vessel).

Results: MLC density was 1.8-fold greater in the PVD group (13.21 ± 7.29 cells/mm^2) compared to the no PVD group (7.48 ± 4.43 cells/mm^2; P = 0.04). MLCs were increased 1.9-fold on-vessel (P = 0.07), 1.9-fold in the perivascular region (P = 0.12), and 2.2-fold in ischemic areas (P = 0.22).

Conclusions: MLCs were detected in both PVD and no PVD eyes, suggesting that MLCs exist in the retina, although we cannot exclude a remnant of the cortical vitreous on the retinal surface. PVD eyes showed a trend toward more MLCs near vessels than ischemic areas, suggesting that MLCs could be extravasating from the vasculature in response to PVD. However, vitreous separation could merely enhance MLC detection. PVD status is an important parameter to consider in future MLC studies.

ABSTRACT BODY:

Purpose: Late-onset retinal degeneration (L-ORD) is an autosomal dominant macular dystrophy with anterior segment involvement, notably long anterior zonules (LAZs). In this study, we aim to analyze LAZs in a cohort of L-ORD patients.

Methods: This prospective, single-center study included patients with a genetic diagnosis of L-ORD from 2011-2016. Imaging included true-color non-mydriatic anterior segment photographs by slit-lamp retroillumination. LAZs were identified, marked and plotted using Matlab (R2021a) (Figure 1). The zonule-free zone (ZFZ) was calculated using the longest LAZ to the pupillary axis scaled to an average pupil size of 12 mm. The LAZs number and location, ZFZ length, iris transillumination defects, pachymetry, and features on gonioscopy were described. Calculations were performed on SPSS (v. 25; IBM) with $p<0.05$.

Results: Twelve eyes from 6 patients (median age = 60.5 years, range 56-70; 4 males) were included (Figure 2); one case (2 eyes) was excluded due to inadequate imaging. LAZ length measurement showed high inter-rater (ICC=0.98; $p< 0.001$) and test-retest repeatability (ICC=0.97; $p<0.001$). There was marked variability in the number of LAZs in the cohort, with a median of 160 (range: 11-372). LAZ prevalence varied with quadrant: superior (39%), inferior (24%), nasal (19%), and temporal (18%). LAZ was strongly correlated between right and left eye ($r=0.98$, $p=0.001$), with no significant difference between eyes ($p=0.34$). Additionally, LAZ was strongly correlated with pachymetry ($r=0.92$; $p=0.01$) and inversely with age ($r=-0.78$; $p<0.05$). Scaled ZFZ had a median of 2.0mm (range:1.3-5.4), without significant differences in size between eyes of patients ($p=0.34$). ZFZ was correlated with age ($r=0.85$; $p=0.03$) but not with total LAZ number ($r=-0.68$; $p=0.14$).

Conclusions: This study validates a method for measuring and counting LAZ in L-ORD. In our cohort LAZs are most prevalent in the superior quadrant. LAZ number and ZFZ were symmetrical between L-ORD eyes. ZFZ is smaller in L-ORD patients compared to previous studies of LAZ. The reduced LAZ count in older patients and increased ZFZ may suggest a decrease in the number of zonules with time with a primary loss of longer LAZ. The LAZ findings require validation in a larger cohort, planned as part of an ongoing longitudinal study.

ABSTRACT BODY:

Purpose: Health Literacy (HL)—the ability to get, understand, and use basic health information and services—is vital to effective care delivery. However, more than 1/4th of US adults are estimated to have inadequate HL, putting them at greater risk for poor health outcomes and high health care costs. This study seeks to quantify health literacy across different ophthalmology clinics and patient education levels.

Methods: In January 2020, routine HL assessment was integrated into the clinic intake performed by ophthalmic technicians in all comprehensive ophthalmology clinics at an academic eye institute as part of a quality improvement initiative. HL was assessed using the Brief Health Literacy Screening (BHLS), an orally administered, validated 3-item survey with each question scored on a five-point Likert scale. A retrospective chart review of adult patients seen at various ophthalmology clinic sites of an academic eye institute from January 2020 to December 2021 was performed. Information collected included basic demographic factors, education level, and HL score. Patients younger than 18 years old were excluded.

Results: A total of 16587 patients qualified for the study. 6.58% of all patients had inadequate HL. Among the individual clinics, Retina (16.13%), Neuro-ophthalmology (11.54%), and Glaucoma (10.15%) had the highest proportion of their patients with inadequate HL. When broken down by patient education level, health literacy was greatest among patients whose highest completed education was less than high school (36.51%) or high school (7.97%) compared to those who completed college (1.96%) or an advanced degree (1.78%). Further details are presented in Table 1.

Conclusions: Over a two-year period at an academic medical center, 6.58% of ophthalmology patients had inadequate health literacy, and inadequate HL was highest among those with less completed formal education.

ABSTRACT BODY:

Purpose: Outer retinal corrugations (ORCs) in rhegmatogenous retinal detachment (RRD) that do not fully resolve prior to reattachment may lead to the development of outer retinal folds which are associated with worse functional outcomes. The purpose of this study is to investigate the dynamic evolution of outer retinal corrugations (ORC) in vivo with optical coherence tomorgraphy (OCT) imaging.

Methods: Prospective cohort study. Eyes with RRD that underwent RRD repair were assessed longitudinally with multimodal imaging at baseline and at frequent intervals for up to 6 weeks post-operatively. The primary objective was to assess differences between RRD eyes with and without ORCs and to formulate a theory on the pathophysiology of ORCs by carefully observing the evolution and resolution of ORCs in vivo with OCT.

Results:

Fifty-seven eyes in 51 patients were assessed and followed. 34 participants were male with mean age of 60.9 (SD 7.77). 34 participants were phakic with baseline logMar visual acuity of 0.919 (SD=1.05). Mean duration of fovea-off of 6.88 days (SD=6.52) with 2.01 (SD=0.83) detached quadrants. 56.1% (32/57) of eyes had ORCs and 43.9% had no ORCs on presentation. All (100%) eyes with ORCs had complete and acute loss of RPE control with a larger extent of RRD (1 quadrant or more) and for a duration of more than 2 days. Although eyes without ORCs had subretinal fluid, the RPE was still in relative control of the subretinal space or the RRD had a duration of less than 2 days in all (100%) cases. This included 10 eyes with chronic non-progressive localized RRDs, 6 eyes with small localized acute RRDs, 5 eyes with residual displaced fluid following successful PnR or SB, and 4 eyes with larger acute RRDs of less than 2 days duration.

Conclusions: This prospective study describes a novel dynamic RPE-control theory of ORCs in RRD. The study demonstrates that more extensive RRD with loss of RPE-control for more than 2 days are more likely to develop ORCs. Clinical observations suggest that exposure of the outer retina to liquefied vitreous leads to the outer retina being more susceptible to deformation. Regaining RPE control following RRD repair results in a reversal of the ORCs. Understanding the pathophysiology of ORCs could lead to a modification of vitreoretinal surgical approach that allow ORCs to resolve prior to reattachment. The presence of ORCs is also suggestive of an open retinal break and absence of RPE control.

TITLE: Subretinal drusenoid deposits is associated with increased risk towards the development of iRORA and cRORA

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Choi, D. Lally, New England Retina Consultants, Springfield, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Hanna Choi: Commercial Relationship: Code N (No Commercial Relationship) | David Lally: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The presence of subretinal drusenoid deposits (SDDs) confers increased risk of the development of geographic atrophy. With the recent consensus definition of OCT-defined atrophy, the purpose of this study was to retrospectively investigate the presence of SDD in the development of iRORA and cRORA in non-exudative AMD eyes.

Methods: Retrospective cohort of patients with intermediate dry AMD in one eye, defined as at least 1 large soft druse (≥125 μm), 5 SDDs, or 5 intermediate drusen (>67μm), with at least 5 years of follow-up were examined. SD-OCT biomarkers, including hyperreflective foci, soft drusen, refractile and cuticular drusen, SDD, subretinal hyperreflective material (SHRM), iRORA, and cRORA were recorded at baseline and at year 5. Eyes with baseline cRORA were excluded. Data was analyzed using the Fisher's exact and t test.

Results: Inclusion criteria was met in 122 eyes (84.79±7.40 years old; Female N=79, follow-up 62.90 (±4.78) months), of which 27% (N=33) developed cRORA at 5 years. iRORA developed in 6.56% (N=8). Baseline SDD was independently associated with iRORA or cRORA development (OR=4.45; p=0.0006). In the 45 eyes with SDD at baseline, 11.11% developed iRORA (N=5) and 46.67% developed cRORA (N=21) at 5 years. In comparison, in eyes without SDD at baseline, 3.90% (N=3) developed iRORA and 15.58% (N=12) developed cRORA.[1] Age and baseline hyperreflective foci (OR=5.37) were also indendently associated with iRORA or cRORA development (both $p<0.0001$) while soft drusen was not (OR = 1.56; p=0.32).

Conclusions: Subretinal drusenoid deposits is associated with greater risk of iRORA or cRORA development at 5 years in intermediate AMD eyes; about half developed cRORA by year 5. SDD may be a potential biomarker for the development of iRORA or cRORA. Further investigations are warranted.

ABSTRACT BODY:

Purpose: IL-2 signals through its heterotrimeric receptor (IL-2R) consisting of the α (CD25), β, and g chains. We previously reported the gene expression of all three IL-2R chains in the cornea. Our purpose is to investigate the existence of corneal epithelial IL-2 signaling.

Methods: Eyes and adnexa of female C57BL/6 mice were collected, snap-frozen in liquid nitrogen. Cryosections were stained with antibodies anti-CD25, IL-2Rβ, and IL-2Rg and digital images were acquired with laser scanning confocal microscopy. Immortalized human corneal epithelial cells were grown for 24 h in media with increasing concentrations of IL-2 (0, 50, 125, 250, 500, or 1000 IU),fixed, and stained with an antibody against Ki67. The number of Ki67+ cells was quantified within 6 non-overlapping fields per well; 3 wells were assessed per variable; the study was repeated twice. Tet-On $Krt12^{rtTA}$ (Keratin 12-reverse tetracycline-trans-activator knock-in), tet-O-Cre, and $CD25^{flox}$ lines were mated to create ternary $Krt12^{rtTA/rtTA}$/tet-O-Cre/$CD25^{flox/flox}$ ($K12^{r/r}$/TC/$CD25^{f/f}$) in which $CD25^{f/f}$ was ablated in corneal epithelium upon doxycycline induction hereafter named $CD25^{D/DCEpi}$. $K12^{r/r}$/TC/$CD25^{f/f}$ without Dox induction and binary $K12^{r/r}$/$CD25^{f/f}$ with dox induction serve as controls. Both male and female experimental mice were subjected to the corneal barrier function assay at eight weeks of age using Oregon-Green-Dextran (OGD) dye (n = 8-16/condition/sex).

Results: In C57BL/6, CD25, IL-2R-β, and IL-2R-g chains were present in the corneal epithelium. There was a significant increase in Ki67+ cells/field at IL-2 doses of 125 and 250 U/mL followed by a plateau at higher concentrations ($P < 0.05$ and $P < 0.01$, respectively) in human corneal epithelial cells in vitro. A significant increase in corneal OGD levels (indicating corneal barrier disruption) was observed only in the female doxycycline-fed $CD25^{D/DCEpi}$ mice compared to the doxycycline-fed binary $K12^{r/r}$/$CD25^{f/f}$ mice and in non-induced $K2^{r/r}$/tet-O-Cre/$CD25^{f/f}$ mice (regular diet-fed mice).

Conclusions: All three chains of the IL-2R are expressed in the corneal epithelium at the protein level. Our results indicate for the first time that IL-2 regulates corneal epithelial cell proliferation in vitro and that disrupting IL-2 signaling in the cornea leads to dry eye disease in vivo. This effect was only seen in female mice. Future studies are needed to delineate the pathways used by IL-2 signaling to influence cornea homeostasis.

TITLE: A Cross-Sectional Prevalence Study of Myopia and High Myopia during COVID-19 Pandemic

SESSION TITLE: Myopia epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Tailor, T.W. Olsen, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Prashant Tailor: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Olsen: Commercial Relationship(s);Code O (Owner):Imacular Regeneration LLC

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has caused societal, behavioral changes that have resulted in increased near work and less outdoor time. These changes may influence myopia progression. We performed a retrospective, cross-sectional prevalence study on the population base in Olmsted County, Minnesota to determine if there are short-term changes in myopia.

Methods: Individuals living in Olmsted County who received ophthalmic care at Mayo Clinic Rochester from 2018 to 2021 were analyzed. Exclusion criteria included 1) visually significant cataract, 2) pseudophakia, 3) prior refractive surgery and 4) Age < 6 years. Manifest refractions were converted to spherical equivalent (SE). Patients with a SE ≤ -0.5 D were classified as myopic while SE ≤ -6.0 D were classified with high myopia. Individual age, sex, visual acuity, and lens prescription data were recorded. An algorithm was designed to estimate prevalence for patients without a manifest refraction utilizing their visual acuity, as was used in the NHANES study[1].

Results: We sampled 11,783 invidiual records (8,413 adults; 3,370 children). In adults from 2018 to 2021, the prevalence of myopia was similar at 61% vs 59% (p=0.3887) and high myopia was also similar at 10% vs 9.9% (p=0.5447). In children from 2018 to 2021, the prevalence of both myopia was similar at 21% vs 17% (p=0.2) and high myopia was also similar at 2.6% and 3.8% (p=.37).

Conclusions: From 2018 to 2021, we did not find any trends in myopia development over a relatively brief, 4-year window in either pediatric or adult patients living in Olmsted County, Minnesota.

ABSTRACT BODY:

Purpose: Dendrite remodeling may occur in stressed or injured retinal ganglion cells (RGC) before apoptosis. Macular inner plexiform layer (IPL) thickness has been proposed as a biomarker for early glaucomatous damage. We compared ganglion cell layer (GCL) and IPL rates of change (RoC) in two patient cohorts with suspected and established glaucoma to test the hypothesis that RoC of IPL may be superior to GCL for detection of early glaucoma damage.

Methods: 64 eyes (46 patients) with suspected glaucoma (GS) and 112 eyes (112 patients) with moderate to severe visual field damage and ≥2 years of follow-up and ≥3 macular OCT scans were recruited. The GS cohort had suspicious optic discs with normal OCT retinal nerve fiber layer thickness at baseline. GCL and IPL measurements from the central 18° of the macula (36 superpixels, 3°×3° each) were exported. A Bayesian linear hierarchical model with random intercepts, slopes, and random variances was fitted to estimate GCL and IPL RoC at superpixels. RoC were normalized by dividing absolute rates by their SD. Normalized RoC and proportions of superpixels with significantly negative RoC for GCL and IPL were compared within the GS and glaucoma groups.

Results: The average (SD) baseline age, mean (SD) follow-up time, and average (SD) number of OCT scans were 61.3 (13.7) years, 3.5 (0.7) years and 4.2 (1.0) scans, respectively, in the GS group and 66.9 (8.5) years, 3.6 (0.4) years and 7.3 (1.1) scans in the glaucoma group. In the GS group, the mean normalized RoC (averaged across all superpixels) was faster for GCL than IPL (0.66 vs.0.32 SD unit per year). In 24 out of 36 superpixels, average GCL RoC was significantly negative while only 8 out of 36 superpixels showed significant negative IPL RoC ($p=0.003$)(Fig.1). In the glaucoma group, the mean normalized RoC was faster for IPL than GCL (0.46 vs.0.28 SD unit per year). 13 out of 36 and 23 out of 36 superpixels had significant negative RoC for GCL and IPL, respectively ($p=0.006$)(Fig.1).

Conclusions: GCL thickness is more likely to demonstrate significant negative slopes compared to IPL in very early stages of glaucoma. In contrast, in eyes with established glaucoma, the IPL change rates tended to provide more information(Fig.2). These results confirm our prior findings based on cross-sectional data. The sum of GCL and IPL thickness may provide a stronger signal to detect change in the macula.

SUBMITTER (NAME ONLY): Mark Kleinman

TITLE: Acetyl-histone profiling of degenerating RPE after selective HDAC1/2 inhibition

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.E. Kleinman, R. Dubey, K. jung, A. Davila, S.K. Dubey, Surgery, East Tennessee State University, Johnson City, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Mark Kleinman: Commercial Relationship: Code N (No Commercial Relationship) | Rashmi Dubey: Commercial Relationship: Code N (No Commercial Relationship) | kyung sik jung: Commercial Relationship: Code N (No Commercial Relationship) | Alex Davila: Commercial Relationship: Code N (No Commercial Relationship) | Sushil Dubey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Preliminary data demonstrate significant down-regulation of HDAC1/2 expression in the RPE of eyes with atrophic age-related macular degeneration (AMD). RPE cytotoxicity and patterned inflammatory gene expression were observed after Class I HDAC inhibition in vitro and in vivo. In this study, we investigated the cellular effects of a potent HDAC1/2 inhibitor, romidepsin, on RPE cell viability and interrogated unique signatures of acetyl-histone marks.

Methods: Short term and long-term (>21d) primary human RPE (hRPE) isolates (n=3, Lonza) and ARPE19 cultures were exposed to a dose range of romidepsin (0.1/0.5/1 ng/mL, Selleck). Cell viability was assessed using MTS assay (AQueous One, Promega, measurement of trans-epithelial resistance (TER) and evaluation of tight-junction by ZO-1 immunofluorescence. Levels of histone acetylation (H3Ac/H4Ac) were measured by Western Blotting while specific acetyl-histone marks were evaluated by multiplex assay (EpiGentek). Statistical analyses were performed with ANOVA and Mann-Whitney U test.

Results: Romidepsin induced a dose-dependent loss of RPE cell viability by MTS assay ($P<0.05$) in both short-term and long-term RPE cultures with decreased TER ($P<0.05$) and degradation of ZO-1 tight junctions. Western blotting revealed significantly upgregulated H3ac and H4ac levels after romidepsin treatment (12/24h, $P<0.05$). Multiplex assays identified a specific acetyl-histone signature with elevated levels of H3k14ac, H3k18ac, H4k8ac and H4k16ac.

Conclusions: Class I HDAC expression is critical for RPE homeostasis and cell viability. Targeted inhibition of HDAC1/2 with romidepsin leads to loss of cell viability, decreased TER, disorganized tight junctions in long-term hRPE cultures. There is robust upregulation of acetylated H3/H4 with a specific signature of acetyl-histone marks that may be critical in the epigenetic regulation of RPE cell death. These histone marks may be important in signaling pathways of RPE degeneration that occur during progression of atrophic AMD and may serve as novel targets for AMD therapeutics.

SUBMITTER (NAME ONLY): Christine Xu

TITLE: Risk factors and outcomes of glaucoma following cataract surgery in infancy for persistent fetal vasculature (PFV)-related cataract

SESSION TITLE: Pediatric Ophthalmology Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Xu, Harvard Medical School, Boston, Massachusetts, UNITED STATES|D. Vanderveen, B. Gangwani, I. Oke, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Christine Xu: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Vanderveen: Commercial Relationship: Code N (No Commercial Relationship) | Bharti Gangwani: Commercial Relationship: Code N (No Commercial Relationship) | Isdin Oke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a common complication following cataract surgery in patients with persistent fetal vasculature (PFV). We aim to identify risk factors predisposing to glaucoma in this population and characterize the optic nerve appearance and treatment outcomes.

Methods: This is a retrospective cohort study of patients with PFV-related cataracts at a single tertiary care center. We included all infants who underwent cataract surgery without primary intraocular lens placement before one year of age, with at least five years of follow-up. The primary outcome was a diagnosis of glaucoma or ocular hypertension requiring treatment. Risk factors investigated included age, sex, and the presence of microcornea (horizontal diameter less than 10 mm). Secondary outcomes included type of treatment, optic nerve appearance, and visual acuity. We performed univariate and multivariable regressions and report odds ratios (OR) and 95% confidence intervals (CIs).

Results: 36 eyes from 34 patients were included. The median age at the time of cataract surgery was 1.3 months (Interquartile range [IQR] 1.0-2.2 months). 38% of patients were female and 50% were left eyes. Following surgery, 39% of eyes developed glaucoma or ocular hypertension. The median age of glaucoma diagnosis was 2.5 years (IQR 0.4-6.2 years). The median cup to disc ratio was 0.25 and 50% had visual acuity of 20/200 or worse. All of these patients were treated with topical medication such as timolol, latanoprost, and timolol-dorzolamide. Six of the eyes underwent glaucoma surgery at a median age of 7.5 months (IQR 3.7-45.2 months), most commonly goniotomy and trabeculotomy. Patients who developed glaucoma were more likely to have microcornea (77% vs. 36%, $p = 0.040$) (Table 1). While univariate regression identified microcornea as a significant risk factor for glaucoma in eyes with PFV (OR 4.37, 95% CI 1.08-20.6, $p = 0.046$), after adjusting for age at surgery, microcornea was no longer significant (OR 3.09, 95% CI 0.68-16.0, $p = 0.2$) (Table 2).

Conclusions: Microcornea is frequently observed in the patients with PFV who develop glaucoma or ocular hypertension. A greater understanding of potential risk factors and treatment outcomes can help guide interventions.

TITLE: Quality of Life Analysis in Patients with Retinitis Pigmentosa

SESSION TITLE: Quality of Life Outcomes, Rehabilitation and Training Programs

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Nguyen, J. So, S.M. Duff, S. Grover, J. Chen, Ophthalmology, University of Florida, Florida, UNITED STATES|Y. Song, Indiana University, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Timothy Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Joshua So: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Duff: Commercial Relationship: Code N (No Commercial Relationship) | Yiqing Song: Commercial Relationship: Code N (No Commercial Relationship) | Sandeep Grover: Commercial Relationship: Code N (No Commercial Relationship) | Jinghua Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) is an inherited retinal disease (IRD) with progressive loss of night and peripheral vision. We conducted this survey study to assess the quality of life of patients with RP.

Methods: A questionnaire study was performed on 34 RP patients from the University of Florida Department of Ophthalmology's patient base. Each patient was called over the phone to take part in the survey. Data on education, employment, and medical care status were collected. Each of their responses were then analyzed collectively with other patients' responses.

Results: A total of 34 patients with RP (10 males, 24 females) with a mean age of 55.1 +/- 18.9 were assessed (range, 21-91 years) 76% of patients (26 of 34) noticed visual difficulties under the age of 18. At the time of data collection, one patient was still attending school. Of those who finished school, 33% of patients who graduated (11 of 33) only have a high school diploma, while 58% (19 of 33) have a college degree. Three patients only completed primary education. 11 of the 33 patients reported that they did not finish all the education they had intended to complete. Two of the 11 patients reported that they could not finish their education due to visual difficulties. 42% (14 of 33) of those who were no longer in school were unemployed (9 females, 5 males). Of the 42% who were unemployed, 57% of patients did not have a job due to vision. 33 out of 34 patients (97%) were insured. Of those who were insured, 18% (6 of 33) were not satisfied with their insurance. 29% of patients had financial and visual difficulties obtaining visual aids and only 53% have disability insurance.

Conclusions: The results of our study show that RP may affect the levels of education, employment, and access to medical care. Further studies and statistical analysis, such as obtaining vision, visual field, and optical coherence topography (OCT) data as well as comparing our results to normal population, are required to identify and confirm the contributing factors of the quality of life of patients with RP.

TITLE: Psychometric characteristics and use of 360-degree assessment tool for ophthalmology residents in Indonesia

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y.S. Ningtiyas, S. Sutjipto, Y. Primitasari, E. Komaratih, Department of Ophthalmology, Dr. Soetomo Academic General Hospital - Universitas Airlangga, Surabaya, East Java, INDONESIA|

Commercial Relationships Disclosure: Yuniar Ningtiyas: Commercial Relationship: Code N (No Commercial Relationship) | Sutjipto Sutjipto: Commercial Relationship: Code N (No Commercial Relationship) | Yulia Primitasari: Commercial Relationship: Code N (No Commercial Relationship) | Evelyn Komaratih: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Competency-based medical education requires a robust and multifaceted evaluation system. We performed a cross-sectional study of ophthalmology residents to determine the validity, reliability, and feasibility of 360-degree assessment tool for assessing competency in professionalism, interpersonal and communication skills, and system-based practice.

Methods: A 5-point Likert-type online questionnaire was completed by attendings, nurses and allied health staffs, patients/families, and resident peers after each ophthalmology resident rotation from January 2021 to June 2021. The questionnaire was adapted from the International Council of Ophthalmology (ICO) 360-degree assessment tool. The Indonesian version questionnaire was developed using forward and backward translation.

Results: A total of 534 evaluations were completed for 42 residents. Validity test using Pearson correlation analysis between all combinations of evaluators ranged from 0.51 to 0.94 and all were statistically significant ($p<.01$). The internal consistency reliability of the instrument was a Cronbach's alpha of 0.92, 0.80, 0.86, and 0.93 for attending doctor, nurse and allied health staff, patient/family, and resident peer, respectively. Sixty percent of study participants felt that this assessment contributed positively to the operation of ophthalmology service. All evaluators rated residents highly (mean Likert score range, 3.96 – 4.60). Patient/families rated the resident highest for interpersonal and communication skills (4.54±0.12) and system-based practice (4.60±0.16) among other evaluator groups. Nurse and allied health staff rated resident highest for professionalism (4.58±0.35). Ratings by year of training varied for each competency. No significant differences were found between rating from patient/families and their educational background ($p>.05$).

Conclusions: The 360-degree assessment tool appears to be valid, reliable, and feasible to evaluate ophthalmology residents' competency in professionalism, interpersonal and communication skills, and system-based practice. Information from the assessment may provide multidimensional formative feedback for residents' development and improve residents' performance.

ABSTRACT BODY:

Purpose: To develop a durable, biocompatible, transparent, artificial corneal stromal substitute that would mimic the human corneal stroma in key physical and physiological functions

Methods: a hyaluronic acid (HA)-based 500 μm hydrogel was fabricated and then crosslinked. Compounds ratios as well as crosslinking condition was systematically evaluated by assessing swelling ratio (hydrogel weight after submerging in PBS), mechanical strength (rheometer with cone-and-plate geometry), biodegradability (remaining weight after submerging in an enzyme cocktail), optical transparency (spectrophotometer at UV-Visible wavelengths) and glucose/albumin permeability (glucose and albumin concentration across the hydrogel) of the resulting hydrogels. The hydrogel was then coated with an antiangiogenic compound to prevent neovascularization

Results: all composites were completely clear (>88% transmittance) with refractive index of ~1.3, which is very close to that of the human cornea. Hydrogels were shown to have an equilibrium water content of ~90% with less than 5% degradation in enzymatic solution over 2 months. Tensile strength and maximum elongation of the hydrogels were found to be 1.47 MPa and 8.57% respectively, which are comparable to native cornea. The presence of the specific bonds in the hydrogel structure and the crosslinking of the antiangiogenic compound coating on the walls were confirmed by Fourier Transform Infrared Spectra

Conclusions: We have been able to produce a hyaluronic acid-based co-polymer with optical and mechanical properties similar to the human corneal stroma. Further studies would be needed to test biocompatibility in vitro and in animal models

Lampi, Integrative Biosciences, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Larry David: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Halls: Commercial Relationship: Code N (No Commercial Relationship) | Keith Zientek: Commercial Relationship: Code N (No Commercial Relationship) | Francis Valiyaveetil: Commercial Relationship: Code N (No Commercial Relationship) | Ravikumar Reddi: Commercial Relationship: Code N (No Commercial Relationship) | Kate Haverson: Commercial Relationship: Code N (No Commercial Relationship) | Ujwal Shinde: Commercial Relationship: Code N (No Commercial Relationship) | Kirsten Lampi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a semi-synthetic approach using native chemical ligation to introduce specific sites of age-related modifications into crystallins to examine their impact on protein structure and contribution to cataract.

Methods: An N-terminally SUMO tagged human γS-crystallin containing residues 16-177 was expressed containing a Q16C mutation to act as a ligation site. Following removal of the SUMO tag using ulp-1 protease, the resultant γS 16-177 was solubilized in 6M guanidine and ligated to a synthetic γS 1-15 peptide containing a C-terminal peptide thioester using 4-mercaptophenylacetic acid under reducing conditions, followed by dialysis and purification using cation ion exchange chromatography. Full length γS-crystallin was confirmed by mass spectrometry and proper folding of the protein examined by both CD spectroscopy and hydrogen/deuterium exchange to measure the number of surface exposed amides in the whole protein. The ligated product was also compared to full length bacterially expressed γS Q16C, as well as denatured/refolded γS Q16C, and wild type γS.

Results: The semi-synthetic γS crystallin was successfully created and refolded in its native state as supported by an identical CD spectrum and similar numbers of rapidly exchanging amide residues as fully bacterially expressed versions of wild type γS, Q16C γS, and denatured/refolded Q16C γS.

Conclusions: This is the first known successful use of native protein ligation to create a semi-synthetic crystallin in its native state. The methodology will allow introduction of specific isoaspartate residues in γS at residues D12 and N14, two sites containing isoasp modifications in the insoluble protein of human cataractous lenses. Introduction of these age-related modifications in γS will test whether they contribute to cataract or are merely associative. The technique should prove useful to examine other age-related modifications in crystallins and provide more relevant information than previous studies relying on only in-vitro incubation or mutagenesis.

TITLE: Subthreshold Photocoagulation Treatment of Recurrent Central Serous Chorioretinopathy with Pachychoroid Pigment Epitheliopathy

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Zhang, B. Sun, J. Xie, G. Hou, Shanxi Eye Hospital, Taiyuan, Shanxi, CHINA|

Commercial Relationships Disclosure: Zhaoxia Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Bin Sun: Commercial Relationship: Code N (No Commercial Relationship) | Juan Xie: Commercial Relationship: Code N (No Commercial Relationship) | Guangping Hou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pachychoroid spectrum disorders are characterized by attenuation of the choriocapillaris overlying dilated choroidal veins, and associated with progressive retinal pigment epithelium dysfunction and neovascularization, including central serous chorioretinopathy (CSC) and pachychoroid pigment epitheliopathy (PPE). Subthreshold laser therapy is known to have RPE function as its main target. In this study, we evaluated subthreshold photocoagulation treatment for patients diagnosed with CSC and PPE.

Methods: Participants in this study were 7 patients (7 eyes; 4 males and 3 females) with CSC and PPE, who underwent enhanced depth imaging optical coherence tomography (EDI-OCT), fundus fluorescein angiography (FFA) and indocyanine green angiography (ICGA). Subthreshold photocoagulation was performed to treat pigment epithelial detachment (PED) at site of PPE outside of macular, which was performed with the following parameters: 5% duty cycle, 200 ms pulse duration, 160 μm spot size and 50% power of the barely visible threshold. Best corrected visual acuity (BCVA), the central choroidal thickness (CCT), and choroidal thickness (CT) at the lesion site of PPE were measured during follow-up.

Results: Of 7 eyes with recurrent CSC and PPE (Snellen< 20/40), FFA demonstrated one or multiple focal leaks at the level of RPE in 2 eyes, and multiple indistinct leaks in 5 eyes. ICGA showed multifocal areas of choroidal hyperpermeability as hyperfluorescent patches in the mid phase in all 7 eyes. EDI-OCT revealed macular serous retinal detachment (SRD) and irregular RPE elevation or PED outside of macular, CT increased at the lesion site of SRD and RPE characterized by dilated choroidal vessels in Haller's layer (pachyvessels), accompanied by attenuation of choriocapillaris. After subthreshold photocoagulation at the site of PPE (e.g. PED) outside of macular, with the recovery of SRD and RPE lesion, CCT and CT decreased significantly ($P<0.05$).

Conclusions: In the eyes of recurrent CSC with PPE, subthreshold photocoagulation at the lesion site of PPE can resolve CSC within macular. Simultaneously, pachychoroid at the sites of CSC and PPE also improved. These results may support that PPE and CSC clinically overlap and have a common pathogenic background.

ABSTRACT BODY:

Purpose: To investigate the prevalence of visual acuity impairment and external eye abnormalities in school-aged children in Zimba, Zambia.

Methods: Vision screening was performed in children 5 to 18 years old (grades kindergarten to grade 9) between July-August 2019. The vision screening program involved the assessment of visual acuity, pupil size, colour vision, and reading vision. An external eye examination of the eyelids, orbit, cornea, and iris was also performed. Demographic data collected included patient age and gender. Screening failures were defined as any child presenting with a visual acuity of 20/40 or worse or ≥2-line interocular difference between eyes. Schoolchildren with abnormalities upon external eye examination were also classified as a screening failure. All screening failures were referred to the eye clinic for further assessment.

Results: A total of 676 schoolchildren underwent vision screening. 3.70% (25/676) of schoolchildren did not pass the vision screening program and were referred to the local ophthalmology clinic for further assessment. 1.33% (9/676) of schoolchildren did not pass the vision screening criterion for visual acuity. 2.4% (17/676) did not pass the vision screening criterion based on external eye examination. One student failed both visual acuity and external eye exams. Mild vision impairment (visual acuity between 20/40 to 20/60) was the most common amongst schoolchildren, comprising 55.56% (5/9) of visual acuity failures. Corneal/conjunctival scars were the most common external eye abnormalities amongst schoolchildren, comprising 47.06% (8/17) of external eye exam failures.

Conclusions: Our study is the first to report on visual acuity impairment and external eye abnormalities amongst schoolchildren in rural Zimba, Zambia. A total of 3.70% schoolchildren did not pass the vision screening program and were referred for further ophthalmic assessment. 1.33% of schoolchildren did not pass the vision screening criterion for visual acuity. 2.4% did not pass the vision screening criterion based on external eye examination. Compared to other regions around the world with similar vision screening criterion, a low percentage of schoolchildren failed the visual screening program.

ABSTRACT BODY:

Purpose: To determine the effect of 0.01%, 0.03%, and 0.05% atropine on pupil size and binocular vision function in children aged 6 to 17 years.

Methods: Forty-six children (28 girls and 18 boys) aged 6 to 17 years were randomized into 4 groups: placebo (n= 10), 0.01% (n=13), 0.03% (n= 11), or 0.05% (n= 12) atropine. One drop of atropine was administered into each eye once. The following measurements were collected before applying atropine and 30 minutes, 60 minutes, and 24 hours following application of atropine: pupil size in bright and dim illumination, associated phoria by cover test at distance and near, near point of convergence (NPC) break and recovery, 5 times repeat of NPC (stamina), NPC through red and green glasses (fragility), negative fusional vergence at near, and positive fusional vergence at near. Repeated measures ANOVA with post hoc comparison was performed to determine the effect of 0.01%, 0.03%, and 0.05% atropine eye drops on binocular vision measurement at each time point.

Results: The mean age of participants was 10.73 ±3.01 years. Average spherical equivalence by cycloplegic refraction was -1.70 ± 1.98 D and -1.72 ± 2.10 D, OD and OS respectively. Difference in pupil diameters in bright and dim illumination was statistically significant when comparing all 3 atropine groups to placebo group over time ($P < 0.001$). Atropine eye drops had the most effect on pupil diameter 60 mins after installation ($P<0.001$). Pupil diameter was partially recovered at 24 hours with no statistical significance compared to the 30-minute time point ($P >0.05$), although still significantly different from baseline in the 0.03% atropine group ($P=0.002$). In the 0.01% and 0.05% atropine groups pupil diameter fully recovered after 24 hours with no significant difference from baseline ($Ps>0.05$). There was no significant difference in binocular vision measurements including associated phoria, NPC, NPC stamina and fragility, negative fusional vergence, and positive fusional vergence(all Ps >0.05)

Conclusions: Pupil size was significantly enlarged by 0.01%, 0.03%, and 0.05% atropine in both dim and bright illumination with more effect at 60 minutes after application. However, low dose atropine eye drops have no effect on binocular vision measurements. Thus, in respect to binocular vision, it is relatively safe to use low-dose atropine to treat myopia progression in children aged 6 to 17 years.

ABSTRACT BODY:

Purpose: To examine the academic background, scholarly activity, and demographic characteristics of pediatric ophthalmology program directors (PDs) through cross-sectional analysis.

Methods: All pediatric ophthalmology PDs of fellowship programs that participated in the San Francisco Match in January 2020 were included. Information was collected through online search of publicly available sources from July 7th, 2021 to July 23rd, 2021. Scholarly activity was measured by the number of peer-reviewed articles published as well as the Hirsch index.

Results: Of the 43 pediatric ophthalmology fellowship programs reviewed, 22 (51%) had a male PD, and 21 (49%) had a female PD. The mean age of current PDs was 53.5 ± 8.8 years old. The average age at time of appointment was 39.2 ± 7.7 years old. There was a significant difference between the current age of female PDs (49 ± 7.3) and male PDs (57.8 ± 8; $P < 0.0001$).

Thirty-eight (88%) PDs attended medical school in the United States. Forty-two have an MD (98%) and one (2%) has an MBBCh. Thirty-nine (91%) PDs completed ophthalmology residency in the U.S. Forty-two (98%) completed a fellowship in pediatric ophthalmology in the U.S. Ten (23%) of the PDs were dual fellowship trained.

The average number of peer-reviewed publications published by each pediatric ophthalmology PD was 62 ± 77.4 (median 31, range 3-299). There was a statistically significantly higher Hirsch-index among male PDs (23.9 ± 15.7) than female PDs (10.3 ± 10.1; $P = 0.0017$). There also was a higher number of peer-reviewed publications for male PDs (91 ± 89) than female PDs (31.5 ± 48.6; $P = 0.0099$).

Conclusions: Pediatric ophthalmology fellowship programs have equal representation of male and female program directors. This is unique to this subspecialty as women continue to be underrepresented in ophthalmology. The reasons for higher scholarly output of male versus female PDs is unclear, and further research will be helpful to address this disparity.

TITLE: Understanding the role of MYB in LGACC in developed in-vitro model

SESSION TITLE: Tumor - Diagnosis, prognosis, and molecular mechanism

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.H. Moeyersoms, D. Pelaez, Cancer Biology, University of Miami, Coral Gables, Florida, UNITED STATES|D. Pelaez, Biomedical Engineering, University of Miami, Coral Gables, Florida, UNITED STATES|

Commercial Relationships Disclosure: Acadia Moeyersoms: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Pelaez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lacrimal gland adenoid cystic carcinoma (LGACC) is a rare but highly lethal indolent cancer originating in the cells of secretory glands, primarily of the head and neck. With the 10-year survival rate of 20%, the only life extending technique is to remove the eye and surrounding socket contents followed by extensive chemoradiation. Despite radical treatment, LGACC has a poorer prognosis than head and neck adenoid cystic carcinoma (ACC) in part due to its propensity for perineural invasion, and hematogenous and intracranial spread. Extensive genome analysis of adenoid cystic carcinoma (ACC) of the head and neck has uncovered a high mutation rate of MYB that leads to overexpression. This event is thought to be the key driving mutation of ACC that has been well characterized in tissue samples. A pressing issue in the field of ACC research is the loss of MYB expression in cell lines developed from tumor tissue. As MYB overexpression is a key characteristic of ACC, it is important for cell line models to maintain the overexpression. Here, we develop the tools and cell lines essential for the molecular and in vitro characterization of MYB in LGACC.

Methods: We completed RNA sequencing on our 12 LGACC cell lines and identified a loss of MYB expression, consistent with head and neck ACC cell lines. To address this issue, we transduced 3 LGACC and 3 normal lacrimal gland cell lines with a dual vector system that includes tet-inducible MYB expression to reintroduce its overexpression in the LGACC cells. We validated MYB overexpression via RT-qPCR and western blot. We completed RNA sequencing on our newly developed cell lines and have studied the effects of reintroducing MYB expression in migration and proliferation assays.

Results: We developed new LGACC cell lines with inducible MYB expression, essential for downstream in vitro characterization of this key molecular driver underlying cancer progression in patients. We characterized how the overexpression of MYB in normal and LGACC cells changes the proliferation and migration.

Conclusions: To advance the understanding and treatment of LGACC, there is a need for a validated model to be able to LGACC in-vitro. We have developed cell line models that have regained the main driver of ACC. This now allows us to further understand the role of MYB in LGACC progression and have a model to test treatments.

ABSTRACT BODY:

Purpose: Identify potential pathogenic mutations in the Frizzled 4 gene (FZD4) in patients with clinically diagnosed Familial Exudative Vitreo-Retinopathy (FEVR). FEVR is caused by variants impacting several genes including the FZD4 gene. FZD4 is the central cognate receptor for Norrin WNT signaling in the human retinal endothelium. 76 subjects diagnosed with FEVR, and near relatives, were sequenced using a custom Ampliseq panel that includes eight genes related to FEVR/ND and Retinoschisis (NDP, CTNNB1, TSPAN12, KIF11, FZD4, LRP5, ZNF408, RS1).

Methods: A custom Ampliseq targeted panel (180 amplicons) for 8 genes was designed with Illumina's Design Studio. The targeted panel used three pools (PCR reactions) per patient sample for complete coverage of 83 exons with 25 bp of adjacent intron sequence. Targeted Genes were: NDP (ChrX), RS1 (Chr10); CTNNB1 (Chr3); TSPAN12 (Chr7); KIF11 (Chr10), FZD4 (Chr11), LRP5 (Chr11), and ZNF408 (Chr11). Ampliseq libraries were sequenced on the Illumina iSeq-100 platform. Variant impacts and allele frequency data were obtained from ClinVar and The Genome Aggregation Databases (gnomAD).

Results: 33 protein-altering variants were found in six FEVR/Norrie Disease related genes. Of note, 9/33 (27.3%) of the variants were present in the FZD4 gene. The 9 variants included 1 pathogenic, 1 novel pathogenic variant (Cys450Ter) and 3 of uncertain significance. 95.5% of the base reads were > Q30 quality, the percent on-target bases passing filer was 92.2%, and the average sequencing depth coverage for the entire panel was 978.

Conclusions: Our custom targeted-sequencing panel was developed with the intention to detect gene variants associated with FEVR, Norrie Disease and Retinoschisis. The panel’s sequencing coverage was of sufficient depth to detect protein-altering variants in the FZD4 gene and to determine variant zygosity.

ABSTRACT BODY:

Purpose: Mitochondrially Derived Peptides (MDPs) are short peptides encoded off the short open reading frames (sORF) of human mitochondrial DNA. Humanin (HN), a 24 amino acid MDP has both in vitro and in vivo benefits improving cell survival. Humanin-G (HNG) has a serine-to-glycine substitution at position 14, making it a 1000-fold more potent variant. We hypothesized that subconjunctival injection of HNG loaded microspheres (HNG-MS) would improve retinal function and alter gene expression in both RPE and retina of treated RCS rats.

Methods: 21 day old RCS rats received subconjunctival injections in both eyes of (1) 286µg Empty-MS in 100µL Buffered Saline Solution (BSS) (N=6); (2) 286µg HNG-MS in 100µL BSS (N=5); or (3) received no injection (N=6). Functional Analyses. Scotopic & Photopic Threshold Response Electroretinography (ERGs) was performed at 14 and 27 Days After Starting Treatment (DAST). Molecular Analyses. Animals were sacrificed after 4 weeks. One eye was used for immunohistochemistry (IHC), and the other for eye for RNA extraction and gene expression analysis (qRT-PCR). Statistical analysis was performed using Graphpad Prism, using Mann-Whitney U. The significance set at $p<0.05$.

Results: Subconjunctival injections of HNG-MS significantly improved the ERG Scotopic A-wave (166% increase, P=0.0057) compared to the Empty-MS treated RCS rats. The Scotopic B-wave trended towards improvement but did not reach significance (59% increase, P=0.0668). (HNG-MS, n=4; Empty-MS, n=6; NT (n=2). (Fig.1) At 30 DAST with HNG-MS, in neuroretinal cells there was decreased expression of inflammation genes (TNFa 0.53-fold, P=0.032; IL1B, 0.47-fold, P=0.009; CCL2, 0.64-fold, P=0.016) (Fig. 2); In RPE cells, there was decreased expression of apoptosis genes (DDIT3, 0.78-fold, P=0.03; CASP3, 0.7-fold P=0.016; CASP7, 0.77-fold, P=0.029; CASP9, 0.77-fold P=0.016) (Fig. 3), along with antioxidant (SOD2, 0.64-fold P=0.016) and inflammatory genes (TNFa, 0.11-fold, P=0.029; IL1B, 0.25-fold, P=0.004) (Fig. 4). Significance of gene expression values for HNG-MS compared with Empty-MS.

Conclusions: The subconjunctival injection of HNG-MS provides significant improvement in retinal function and beneficial impact on gene expression in RPE and neuroretina of RCS rats. This supports our hypothesis that HNG loaded microspheres can serve as an effective delivery method for HNG in models of retinal degeneration.

Fonseca-Aguirre: Commercial Relationship: Code N (No Commercial Relationship) | Pedro-Iván Navarro: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This cross-sectional study included patients diagnosed with senile cataracts who underwent FLACS at the Anterior Segment Surgery Department, Asociación para Evitar la Ceguera en México I.A.P., Mexico City, Mexico. Included patients were assigned to two groups for either the Gravity-Fluidics system (Infiniti® Vision System) or Active-Fluidics (Centurion® Vision System) for routine phacoemulsification.

Methods: Lens epithelial cells (LECs) were obtained from the anterior capsule of type-two diabetic patients undergoing phacoemulsification surgery. All subjects were divided into two groups. Group 1 comprised T2DM patients without Proliferative Diabetic Retinopathy (PDR) and Group 2 T2DM patients with mild and moderate PDR. Immunofluorescence determined the expression of TGFß1, TGFß2, IL-1ß, IL-6, and MMP-9.

All values are expressed as means ± SD (Standard Deviation). According to data distribution, the significance between groups was evaluated using a Students-T-test or the Mann-Whitney test. Differences were defined as significant at $P < 0.05$. Gaussian distribution was determined using the D'Agostino-Pearson omnibus normality test for all variables. The SPSS 20.0 evaluated significance and GraphPad Prism 8 was used to generate figures and plots.

Results: A total of 74 eyes underwent cataract removal. Thirty-five patients were in the Gravity-Fluidics System group and thirty-nine in the Active-Fluidics System. We found a median CDE of 4.42 ± 7.92 (IQR) for the Gravity-Fluidics System group. Also, a mean phaco time of 15.88 ± 18.06, 436.3 ± 129.5 mean aspiration time, and estimated fluid of 85.74 ± 25.35. For the Active-Fluidics System group, a median of 4.81 ± 2.26 CDE ($p=0.908$), 70.96±45.19 phaco time ($P <0.001$), 413 ± 176.4 aspiration time ($p= 0.130$), and a 103 ± 52.57 estimated fluid was measured. aspiration time ($P= 0.130$) and estimated fluid ($P= 0.306$)

Conclusions: All main variables were comparable between Gravity-Fluidics and Active-Fluidic systems undergoing FLACS. CDE measurement, aspiration time, and estimated fluid failed to demonstrate statistically significant differences between groups.[MOU1] Moreover, all parameters also evidenced a good level of agreement, showing a narrow-width variability, except for CDE estimates for dense cataracts in the Bland-Altman analysis.

Commercial Relationships Disclosure: Archana Boga: Commercial Relationship: Code N (No Commercial Relationship) | Fiona Stapleton: Commercial Relationship: Code N (No Commercial Relationship) | Michael Chapman: Commercial Relationship: Code N (No Commercial Relationship) | Blanka Golebiowski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: Altered oestrogen levels may play a role in the pathophysiology of dry eye in women. During IVF (in vitro fertilisation) treatment, circulating oestrogen levels increase 10-50x, providing a platform to observe the effects of systemic oestrogen on dry eye symptoms and signs. This study examined changes in ocular pain and in symptoms and signs of dry eye with IVF treatment and the relationship between sex hormones and ocular symptoms and signs.

Methods: Methods: A 2 visit study of women undergoing antagonist IVF treatment was conducted. The baseline visit was on the first day of menstruation when oestrogen levels are lowest, and the peak oestrogen visit was on day 9-11 of the treatment. Symptoms were examined using the Ocular Surface Disease Index (OSDI), Meibomian Gland Dysfunction specific questionnaire (MGD-14), Instant Ocular Symptoms Score (IOSS) and Ocular Pain Assessment Survey (OPAS). Signs of dry eye including Non-Invasive Breakup Time (NIBUT), Phenol Red Thread (PRT), meibomian gland grading and ocular surface staining were assessed. Serum levels of a panel of sex hormones, their precursors, and metabolites were assessed using mass spectrometry and immunoassay methods. Wilcoxon signed-rank test was used to assess changes in symptoms and signs. Spearman and Pearson correlations were used to evaluate association between sex hormones and symptoms and signs.

Results: Results: 40 women (36.2 ± 4.0 years) completed the study. Baseline oestradiol levels were 28.9 pg/ml (20) (median (IQR)) and peak oestradiol levels were 1360 pg/ml (1276). OPAS and SANDE scores worsened ($p=0.02$ and $p<0.01$) and NIBUT and PRT values decreased ($p=0.005$ and 0.01) at peak oestrogen visit relative to baseline. Higher oestradiol (E2) and lower luteinising hormone (LH) were associated with worsening of OSDI scores (rho = 0.34 $p=0.03$, rho= -0.49 $p=0.001$). A greater oestradiol to testosterone (E2: T) ratio was associated with shorter NIBUT (rho= -0.32, $p=0.04$) and lower progesterone (P4) was associated with greater ocular pain (rho= 0.39, $p=0.01$).

Conclusions: Conclusions: An extreme rise in oestradiol levels and changes in other sex hormones (E2: T, LH, P4) during IVF treatment resulted in increased symptoms of ocular dryness, ocular pain, and tear film alterations analogous to mild dry eye. Ocular surface symptoms and clinical signs were higher at peak oestrogen visit, but the change was not clinically significant.

TITLE: Protective role of AIBP in glaucomatous retinal ganglion cells and their axons

SESSION TITLE: Neuroprotection and Neuroregeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Ju, Ophthalmology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure: Wonkyu Ju: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The goal of this study is to investigate the effect of Apolipoprotein A-I binding protein (AIBP; gene name APOAIBP) on retinal ganglion cell survival and central visual pathway preservation in a mouse model of glaucoma

Methods: Human retina tissues sections were obtained from a normal human donor or patients with glaucoma. Five mo-old Pre-glaucomatous DBA/2J (D2) mice eyes were intravitreally transduced with recombinant adeno-associated virus serotype 2 (AAV2) constructs including AAV2-Null or AIBP for 5 months. Each of the 10-mo-old D2 mice used in this study had a single IOP measurement. RGC survival and its axon preservation were assessed by cell counting and RBPMS or NF68 immunohistochemistry. The microglial alteration was measured by IBA1 immunohistochemistry. The preservation of the central visual pathway was assessed in the superior colliculus (SC) by labeling with cholera toxin submit B (CTB).

Results: We found that RGC soma and axons were the primary sites of AIBP expression in the normal retina from a human donor. In contrast, AIBP immunoreactivity was significantly decreased in the RGC somas in glaucomatous human retinas. In 10-mo-old glaucomatous D2 mice, we found that cholesterol content was significantly elevated in the inner retinal layer, and expression of AIBP and ABCA1 was significantly decreased – by half – compared to age-matched control D2-Gpnmb^{+} mice. Based on these data, we overexpressed AIBP in the retina by in vivo delivery of AAV-AIBP. Our results demonstrated that overexpression of AIBP significantly protected RGCs in the middle and peripheral retinas and preserved their axons in the glial lamina of 10-mo-old glaucomatous D2 mice. We also found that overexpression of AIBP significantly increased microglial branch length and the number of endpoints in the middle area of the retina in 10-mo-old glaucomatous D2 mice. However, there were no changes in soma size and number of IBA1-positive microglia. Using CTB labeling, we found that 10-mo-old glaucomatous D2 mice had decreased CTB density in the SC. Surprisingly, we also found that overexpression of AIBP significantly increased CTB density in the SC of 10-mo-old glaucomatous D2 mice.

Conclusions: These findings suggest the possibility that AIBP has a therapeutic potential to treat glaucoma and other optic neuropathies

ABSTRACT BODY:

Purpose: To evaluate pharmacologic liver X receptor agonism in human corneal epithelial cells and in a murine model for dry eye disease.

Methods: Human corneal epithelial (HCE-T) cells were seeded in 8-chamber slides grown to confluency. Cells were pre-treated with DMSO (vehicle) and or ouabagenin (0.05 µM in DMSO). One hour later, cells were exposed to hyperosmolar conditions by supplementation with a dose-range of NaCl (0 - 75 mM). after 24 h, tight junction organization was quantified by anti-zona occludens 1 (ZO-1) immunostaining. For in vivo studies, the liver X receptor agonist, T-0901317, was encapsulated into poly (lactide-co-glycolide) nanoparticles (PLGA NP). Dry eye disease was induced using the SiccaSystem® desiccating stress environment combined with transdermal administration of scopolamine to inhibit lacrimal gland exocrine function for a period of 14 d. Concomitantly, mice were treated three times daily by topical application (10 µl) with either empty PLGA NP or T-0901317-encapsulating PLGA NP. Corneal fluorescein staining was performed to assess corneal damage.

Results: Hyperosmolar stress resulted in ~30% decreased ZO-1 immunoreactivity ($P < 0.05$) and significantly reduced tight junction organization index (TiJOR). Treatment with ouabagenin fully protected against loss of ZO-1 immunoreactivity and disorganization of cellular tight junctions. Desiccating stress/ scopolamine-induced corneal damage was significantly lower in T-0901317-encapsulating PLGA NP-treated eyes (median score: 1, range 0 – 3) compared with vehicle-treated eyes (median score: 2, range 1 – 4; n= 16; $P < 0.05$).

Conclusions: LXR agonists, oubagenin and T-0901317, improve dry eye disease pathology in vitro and in vivo. These data support feasibility of the ongoing development of LXR agonists for the treatment of dry eye disease.

ABSTRACT BODY:

Purpose: To evaluate incidence and clinical characteristics of eyes that exhibit recurrent glaucomatous visual field progression during follow-up.

Methods: This study included 12,402 standard automated perimetry (SAP) tests of 1,070 eyes of 734 subjects from the Duke Glaucoma Registry (DGR). Eyes were followed for at least 5 years with a minimum of 7 reliable SAP 24-2 tests. Progression was determined by event-based analysis using the Guided Progression Analysis (GPA, Carl-Zeiss Meditec). At the time of each event of progression, the baseline visual field tests used for reference were reset and the GPA was subsequently reapplied until the end of follow-up. Similarly, risk factors such as mean and peak intraocular pressure (IOP) were revaluated to reflect each interval leading to the next event or end of follow-up. Survival analysis for recurrent events was used to evaluate risk factors for progression.

Results: Mean follow-up time was 8.5±2.9 years, with an average of 11.6±5.5 (range: 7 to 40) SAP tests per eye. A total of 375 events of progression occurred in the population during follow-up; 279 (26%) eyes had at least 1 event, of which 76 (27%) eyes presented a recurrence and 18 (6%) eyes presented a second recurrence. The cumulative probability of showing recurrent progression at 5 years was 13% and at 10 years was 63%. Eyes with recurrent progression tended to exhibit accelerated rates of progression in the interval leading to recurrence, with average rate of SAP MD of -0.45±0.17dB/year until the first event vs. -0.95±0.81dB/year between the first and the second event ($P<0.001$). Baseline MD (HR: 1.08; 95%CI: 1.05 to 1.12 per 1 dB lower; $P<0.001$), male gender (HR: 1.76; 95%CI: 1.05 to 2.95; $P=0.033$), and age (HR: 1.66; 95%CI 1.30 to 2.11 per decade older; $P<0.001$), were significantly associated with increased risk of recurrence in the multivariable analysis.

Conclusions: In this study with a large clinical population, approximately a quarter of eyes with glaucoma with a previous event of progression presented at least a second event during follow-up. The second episode of progression had, on average, faster rates of visual field loss than the first. Lower baseline MD, male gender, and older age were significant risk factors for recurrent progression.

ABSTRACT BODY:

Purpose: Increased cupping is a sign of glaucomatous optic neuropathy. It is clinically measured using the cup-to-disc ratio (CDR). Similarly, retinal nerve fiber layer (RNFL) loss is associated with disease severity. Due to the similarities in their visual systems and anatomy to humans, rhesus macaques (Macaca mulatta) often serve as a model in ophthalmology research. The purpose of this study was to evaluate the relationship between RNFL thickness and cupping in adult rhesus macaques.

Methods: A total of 52 adult animals were studied (42 females and 10 males), from all ages (range 3.3 to 25.6 years old), which were part of two social groups with high rates of ocular pathologies previously identified. Animals underwent a comprehensive eye exam, including slit-lamp biomicroscopy, pachymetry, axial length measurement, fundus photography and optical coherence tomography (OCT). CDR was determined independently by two experienced glaucoma specialists in a masked fashion from non-stereoscopic digital fundus images. The circumpapillary global and quadrant RNFL thickness was analyzed using a custom automated segmentation software. Eyes were also grouped into those with low CDR (<0.5) and those with high CDR (≥0.5). The relationship of CDR and RNFL was investigated by multilevel mixed-effects models adjusted for axial length, age, and weight.

Results: CDR ranged from 0.2 to 0.75. No statistically significant effect was detected for axial length (mean 19.57±0.57 mm), age (mean 14.5±3.3 years), weight (mean 10.6±2.9 kg) or CDR on RNFL thickness. When eyes were grouped by their CDR, no significant correlation was detected between CDR and global RNFL thickness. However, a significant correlation between CDR and RNFL thickness in the superior quadrant was found ($r = -0.068$, $p < 0.05$). Similar correlations were not detected for RNFL thickness in the inferior, nasal or temporal quadrants.

Conclusions: Higher cup-to-disc ratio is associated with increased superior RNFL loss in rhesus macaques. The CDR in rhesus macaques is likely smaller than in humans, even in animals with substantial RNFL loss, which should be tested in future studies.

ABSTRACT BODY:

Purpose: Best vitelliform macular dystrophy (BVMD) is one of the most common causes of inherited macular dystrophy. Although choroidal neovascularization (CNV) is usually associated with advanced stages of the disease, the detection of CNV in the context of a vitelliform lesion can be difficult using older imaging modalities such as fluorescein angiography. In this study, we use swept-source optical coherence tomography angiography (SS-OCTA) to evaluate the presence of CNV and to correlate structural features that may be useful for CNV detection.

Methods: This was an IRB-approved retrospective review of consecutive patients with molecularly-confirmed BVMD imaged with SS-OCTA (PLEX Elite 9000, Carl-Zeiss Meditec Inc, Dublin, California) at the University of Iowa from September 2017 to July 2020. Clinical data including age, gender, best-corrected visual acuity (BCVA), and prior clinical diagnosis of CNV (i.e., determined without SS-OCTA) were recorded. Structural features including the presence of intraretinal fluid, subretinal fluid, nodular subretinal pillar, focal choroidal excavation, or outer retinal atrophy were identified, and the presence of CNV was also assessed using 6 mm x 6 mm fovea-centered scans by expert graders. Structural features were correlated with the presence or absence of CNV on SS-OCTA using Pearson correlation with p-value <0.05 considered statistically significant.

Results: A total of 53 eyes from 27 patients (13 female; 48.1%) were included for analysis. The average age was 45 years old (range 8-79), and the mean LogMAR BCVA was 0.38 (range 0-1). A total of 14 eyes (26.4%) had a clinical diagnosis of CNV, whereas evaluation by SS-OCTA revealed the presence of CNV in 27 eyes (50.9%). Structural features potentially associated with CNV including interstitial fluid (14 eyes; 26.4%), focal choroidal excavation (8 eyes, 15.1%), nodular pillar (8 eyes; 15.1%) and outer retinal atrophy (21 eyes; 39.6%) were seen relatively frequently. Of these, the presence of focal choroidal excavation and nodular pillar were both independently correlated with the presence of CNV on SS-OCTA ($p<0.01$).

Conclusions: CNV is relatively common in eyes of patients with BVMD. SS-OCTA is a useful tool for CNV detection, and the presence of focal choroidal excavation or nodular pillars should heighten clinical suspicion for the presence of CNV.

TITLE: Periocular melanoma-in-situ treated by Mohs micrographic surgery compared to wide local excision

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Miller, A.C. Jiang, A. Endicott, M. Ahmad, R. Kersten, B. Winn, R. Vagefi, S.R. Grob, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Amanda Miller: Commercial Relationship: Code N (No Commercial Relationship) | Alice Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Alyson Endicott: Commercial Relationship: Code N (No Commercial Relationship) | Meleha Ahmad: Commercial Relationship: Code N (No Commercial Relationship) | Robert Kersten: Commercial Relationship: Code N (No Commercial Relationship) | Bryan Winn: Commercial Relationship: Code N (No Commercial Relationship) | Reza Vagefi: Commercial Relationship: Code N (No Commercial Relationship) | Seanna Grob: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Standard treatment for melanoma in-situ (MIS) has been wide local excision (WLE). More recently, Mohs micrographic surgery has been utilized as an alternative with the benefits of frozen section margin control and its tissue sparing nature in critical anatomic locations, such as the periocular area. Herein, the authors compare WLE versus Mohs surgery in the treatment of MIS and evaluate clinical and surgical characteristics.

Methods: A retrospective review of 347 patients ≥18 years of age was obtained through a UCSF Research Database Search for patients with periocular MIS treated with WLE or Mohs with reconstruction between 2010 and 2019. On further review, 57 met inclusion criteria. The study excluded patients with purely invasive melanoma, intraocular melanoma, or other cutaneous malignancies. Demographic data, clinical characteristics, surgical treatment including defect size, Mohs or excision technique, reconstruction technique, complications, and recurrence data were obtained.

Results: A total of 57 patients were identified, 52 with periocular MIS and 5 MIS with an invasive component on pathology at initial presentation. Average follow-up time was 62 months. Within 50 patients with purely MIS and known recurrence status, there was a 3.6x increase in recurrence for patients treated first by WLE (57.7%) versus Mohs (12.5%) (p=0.0008, 95%CI[0.220-0.683]). Of 35 patients with measurements available, the average difference between the size of the lesion versus surgical defect for the Mohs group (n=24) was 426.46mm^2, while for the WLE group (n=11) was 1098.18mm^2, representing a 1.6x increase (p=0.295, 95%CI[-2023.69-680.23]), however, the finding was not significant. 79% and 75% of patients required complex repair after Mohs resection and WLE respectively. Complications occurred in 14/26 patients (53.8%) after Mohs and 6/15 (40%) after WLE, this difference was not significant (p=0.393, 95%CI[-0.175-0.452]).

Conclusions: Patients with Mohs for MIS had a lower recurrence rate than those with WLE. Although defect size was smaller for Mohs excision, it was not statistically significant. For either type of resection, complex reconstruction rates were high suggesting importance of involving an oculoplastic surgeon in periocular reconstruction.

TITLE: Cross-Sectional Study Comparing Cone Function in Participants with Intermediate Age-Related Macular Degeneration (iAMD) and in Participants with iAMD and Non-Foveal Nascent Geographic Atrophy (nGA)

SESSION TITLE: AMD Functional Testing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.G. Csaky, Retina Foundation of the Southwest, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Karl Csaky: Commercial Relationship(s);Code C (Consultant/Contractor):Roche/Genentech, Abbvie/Allergan, Novartis, NGM Biopharmaceuticals, Johnson & Johnson, Allexion, Retrotope, Merck & Co.

ABSTRACT BODY:

Purpose: To compare cone function in participants with drusen only intermediate age-related macular degeneration (iAMD) and those with iAMD and non-foveal nascent geographic atrophy (nGA) to determine if a more advanced stage of iAMD has an effect on cone photoreceptors.

Methods: In this cross-sectional study, 60 eyes from 33 participants - 30 with drusen only (15 participants) and 30 (18 participants) with nGA determined by spectral-domain optical coherence tomography (OCT) underwent testing for visual acuity (VA), low-luminance visual acuity (LLVA), qCSF algorithm (area under log CSF (AULCSF) under both standard photopic (90 cd/m2) and low luminance (2.0 log neutral density filter)(LL AULCSF) conditions. Student's t-test was used to compare differences in LLVA, AULCSF and LL AULCSF. Correlations between VA, AULCSF and LL AULCSF were determined using Pearsons' r.

Results: In the iAMD group VA = 81 letters ± 3 (mean ± standard deviation), LLVA = 65 letters ± 4, AULCSF = 0.99 ± 0.0.5 and LL AULCSF = 0.38 ± 0.04 while in the nGA group VA = 77 letters ± 4, LLVA = 61 letters ± 8, AULCSF = 0.87 ± 23 and LL AULCSF = 0.28 ± 0.15. Student t-test demonstrated a significant difference in LL AULCSF (p= .048) but not in LLVA (p= .048) or AULCSF (p= .048). Correlation analysis demonstrated significant relationships between visual acuity and AULCSF in both iAMD and nGA groups (r = 0.83 (p<10-9); (r = 0.61 (p=0.0004) and between VA and LL AULCSF in the in the iAMD group (0.68 (p<10-5) but did not correlate with AULCSF under low luminance conditions (r = 2.9 (p= 0.13) in the nGA group.

Conclusions: Nascent GA may represent a more advanced form of iAMD that can impact preferentially one measure of low luminance = LL AULCSF. As normal vision does not correlate with this measurement this test should be considered for use in clinical trials of iAMD.

TITLE: Comparing targeted azithromycin treatment strategies in a trachoma hyperendemic area

SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Mahmud, J.D. Keenan, T. Lietman, University of California San Francisco School of Medicine, San Francisco, California, UNITED STATES|B.A. Haile, Z. Tadesse, S. Gebresillasie, A. Shiferaw, M. Zerihun, The Carter Center, ETHIOPIA|J.D. Keenan, T. Lietman, University of California San Francisco Department of Ophthalmology, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Hamidah Mahmud: Commercial Relationship: Code N (No Commercial Relationship) | Berhan Haile: Commercial Relationship: Code N (No Commercial Relationship) | Zerihun Tadesse: Commercial Relationship: Code N (No Commercial Relationship) | Sintayehu Gebresillasie: Commercial Relationship: Code N (No Commercial Relationship) | Ayalew Shiferaw: Commercial Relationship: Code N (No Commercial Relationship) | Mulat Zerihun: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Tom Lietman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The World Health Organization (WHO) currently recommends annual mass azithromycin distribution to communities with a prevalence of trachomatous infection above 5%. However, after several rounds of annual mass treatment, the majority of treated individuals are not infected. We performed a cluster-randomized control trial to compare two annual targeted treatment strategies: (1) an age-targeted arm of preschool-aged children (6 months-5 years old), (2) a household-targeted arm of households with children with clinically active trachoma.

Methods: 48 communities in the trachoma hyperendemic area of Amhara, Ethiopia who previously received annual mass azithromycin distribution, were randomized to one of four arms for three years: (1) age-targeted, (2) household-targeted, (3) annual mass azithromycin, (4) stop treatment. The primary outcome of interest was PCR prevalence of ocular chlamydia infection and secondary outcome of interest was clinical trachoma (TF), both observed in children 0-9 years old.

Results: 4100 children 0-9 years old were monitored annually for ocular chlamydia and clinical trachoma. When corrected for baseline, there was no significant difference between the two targeted treatment arms for ocular chlamydia (mean difference (MD) 0.0, 95% CI -0.1 to 0.1, P=0.49) nor clinical trachoma (MD 0.0, 95% CI -0.1 to 0.1, P=0.98). Targeted treatment communities had non-significantly less infection and clinical trachoma than communities that stopped treatment (MD 0.0, 95% CI -0.1 to 0.1, P= 0.37) and (MD 0.0, 95% CI -0.1 to 0.1, P=0.78) respectively. However targeted communities also had non-significantly more infection and clinical trachoma than communities that continued WHO recommended community-wide annual mass azithromycin distribution (MD 0.0, 95% CI -0.1 to 0.1, P=0.85) and (MD 0.0, 95% CI -0.1 to 0.1, P=0.99) respectively.

Conclusions: We did not detect a difference between the age-targeted and household-targeted treatment approaches. However, our results suggest that targeted treatment is superior to stopping annual azithromycin treatment. Although targeted treatment was not enough to eliminate infection in this trachoma hyper-endemic region, even WHO guideline annual mass azithromycin distribution may not be sufficient to eliminate the trachoma burden in this area. Thus, targeted treatment strategies may still be beneficial to less trachoma endemic regions facing antibiotic resistance.

TITLE: Idiosyncratic Effects of Viewing Direction and Real-World Depth on Treated Strabismus Investigated with a Multi-Depth Plane Display

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.P. Smithers, J. Skerswetat, P.J. Bex, Psychology Department, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Samuel Smithers: Commercial Relationship: Code N (No Commercial Relationship) | Jan Skerswetat: Commercial Relationship(s);Code I (Personal Financial Interest):PerZeption Inc.;Code P (Patent):Northeastern University, Boston, USA | Peter Bex: Commercial Relationship(s);Code I (Personal Financial Interest):PerZeption Inc. ;Code P (Patent):Northeastern University, Boston, USA

ABSTRACT BODY:

Purpose: Strabismus is a developmental visual impairment affecting 3-5% of children that can cause impaired binocular vision and a broad range of educational and social disadvantages. Strabismus assessment and treatment prioritizes near-distance primary gaze. To quantify strabismus at multiple gaze directions and depths, we developed a novel multi-depth plane display consisting of three screens at 0.4m, 1.26m and 4m.

Methods: Ocular deviation was measured in seven adults who reported a strabismus diagnosis during childhood and two typically sighted controls. Subjects were shown 27 targets in random order in a 3x3x3 grid with 10° between adjacent targets. While participants fixated on each target, an automated cover test was performed by occluding OS or OD with a LCD shutter for 2.25 sec. A head mounted eye-tracker recorded eye movements at 200Hz, and ocular deviation was calculated from the change in eye pupil position between OS, OD, and OU viewing. An optometrist also conducted a standard prism cover test (PCT) at 1m and 4m.

Results: For the controls, the overall mean deviation ± standard deviation was 0.91° ± 1.3° across gaze direction and depth, and the PCT detected no tropia. Five strabismics had received vision and/or amblyopia therapy and two had undergone surgery. Three of these subjects manifested deviations in the PCT that were correlated with eye tracker deviations at primary gaze. The overall mean ocular deviation of strabismic eyes (the eye with the larger deviation) across all directions and depths ranged from 0.32° ± 0.22° to 7.6° ± 2.3° in vision therapy subjects, and 1.2° ± 1.7° to 3.4° ± 2.1° in surgery subjects. The effect of depth and gaze direction on ocular deviation was highly idiosyncratic, e.g., for one vision therapy subject, deviations ranged from 15.8° ± 1.3° for the bottom right target at 4m to 1.9° ± 0.18° for the top target at 0.4m. In contrast, deviation was <0.4° in all directions and depths in another vision therapy subject.

Conclusions: Ocular deviations are highly dependent on gaze direction and depth in observers with a history of strabismus. Strabismus may manifest away from primary gaze and depth and may differentially impact binocular visual function. Comprehensive assessment of strabismus therefore requires measurement across multiple directions and depths of gaze and may be performed with an automated system.

ABSTRACT BODY:

Purpose: Limited access to eye-care among Latinos can lead to missed Vision Threatening Diseases (VTDs) defined as Age-related Macular Degeneration (AMD), cataracts, Diabetic Retinopathy (DR) and glaucoma. As 50% of the people with VTD's are unaware of their condition made worse during COVID-19, comprehensive eye screenings to assess ocular wellness was implemented using telemedicine, Artificial Intelligence (AI) and robotic consultations.

Methods: State-sponsored screenings were conducted at a church in West New York, NJ (78% Latino, mostly from Colombia) over 3 weekends during the 2021 Pandemic. All participants had received two-dose vaccinations and wore a surgical mask during screenings. Nine first-year medical students and 6 community volunteers took part in the wellness evaluation including: medical history, blood pressure, visual acuity, automated refraction, puff tonometry, 45-degree non-mydriatic retinal photography AI. To confirm findings: 6-micron resolution ocular coherence tomography (OCT) B-scan was performed. Screened subjects had their data reviewed by an onsite ophthalmic grader using a Spanish-speaking interpreter. As 80% of screened subjects are lost to follow-up, remote robotic ophthalmology consultation via HIPAA compliant Wi-Fi was utilized in real-time to connect with an off-site ophthalmologist.

Results: 153 subjects, (71 Female (46%), median age 55) had 127 ocular findings (Table 1) found in 85 (55%) subjects, of which 98% of findings were previously unknown and 40 (47%) classified as VTD. 23(15%) subjects had multiple findings. OCT confirmed 23 cases of AMD and glaucoma. AI referred 39 cases. 36 individuals took part in robotic virtual consults. Findings were: cataracts 70 (45%), glaucoma 32 (20%), and AMD 25(16%). Among those with findings, 82% were uninsured and 90% had >2 years since last eye exam. 32 (32/153) subjects had undertreated or untreated hypertension. 93% were un-familiar with telemedicine.

Conclusions: Latinos without health insurance and ease of access to eyecare may have a higher burden of multi-VTDs. An exception was DR which could be a limitation of population bias. This pilot study supports comprehensive wellness eye screenings that may allow for early detection, confirmation, and referral of single or multiple VTD in high-risk low-income communities. Further studies are needed using larger sample populations.

ABSTRACT BODY:

Purpose: The disruption of COVID-19 has caused differential impacts on vulnerable populations. This study tested the hypothesis that persons with visual impairment in Ann Arbor and Detroit, MI faced increased difficulty in their daily lives since summer 2020 during the pandemic compared to normally sighted individuals.

Methods: We administered the Coronavirus Disability Survey (COV-DIS) to assess general and psychological health, isolation, financial and transportation challenges, information access and instrumental activities of daily living. Our study population included 112 adults recruited from the University of Michigan (UM) Health System and 151 adults recruited from the Henry Ford Health System (HF) in Detroit, MI with moderate or worse visual impairment (<20/60 in better-seeing eye), and 160 age/sex-matched controls (C). The COV-DIS was administered via phone or email. The UM IRB approved this study and all participants provided informed consent.

Results: There were no significant site differences in age or visual acuity of participants. Participants with visual impairment at Henry Ford (VIHF) lived in more disadvantaged neighborhoods (higher Area Deprivation Index) compared with UM participants with visual impairment (VIUM) (66 VIHF 52 VIUM; p<.01). All groups reported similar overall health prior to the pandemic. However, a greater proportion of VIHF participants reported somewhat or much worse health than pre-pandemic compared with VIUM or controls (C) (25% VIHF, 10% VIUM, 12% C; p=.003). Participants with visual impairment had more difficulty accessing medical care since the start of the pandemic (13% VI, 6% C; p=.049). One-quarter of participants reported difficulty obtaining trusted information during the pandemic; those with vision impairment were more likely to find the information hard to understand (10% VI, 3% C; p=.01).

Conclusions: COVID-19 and associated mitigation measures had differential effects on populations with visual impairment. Participants with visual impairment in Detroit were more likely to report a negative impact on their health than participants from Ann Arbor, MI. Those with visual impairment in both locations faced greater challenges accessing medical care and trusted and understandable information related to the pandemic. This information may be helpful for shaping health policy to address the barriers faced by individuals with visual impairment.

ABSTRACT BODY:

Purpose: Transplanting photoreceptors derived from human induced pluripotent stem cells (hiPSC)-retinal organoids have the potential to reverse vision loss in affected individuals. However, the scarcity of available transplantable photoreceptor cells provides an unmet challenge. Hence the goal of our current study was to accelerate and synchronize photoreceptor differentiation in retinal organoids by inhibiting the Notch signaling pathway using a small molecule, PF-30184014 (PF), at different developmental time-points.

Methods: Human iPSC- and ESC (Embryonic stem cells)-derived retinal organoids were treated with 10μM of PF for three days at day 45 (D45), D60, and D90 of differentiation. PF-treated organoids collected at 2-, 4-, and 6-weeks post-treatment were analyzed for progenitor and photoreceptor markers by immunohistochemistry (IHC; n=3-5 organoids from 3 independent experiments) and bulk RNA-seq (n=3-5 organoids from 3 independent experiments).

Results: PF-treated retinal organoids collected at 2-weeks post-treatment (at all time-points of differentiation), showed a decrease in progenitor markers (KI67, VSX2, PAX6, and LHX2) and an increase in differentiated photoreceptor precursor markers (OTX2 and CRX). PF-treated organoids at D45 and D60 exhibited an increase in cone photoreceptor markers (RCVRN, RXRG, and ARR3). PF-treatment at D90 revealed an increase in rod photoreceptors markers (RCVRN, NRL, and NR2E3). Bulk RNA-seq analysis mirrored the IHC data.

Conclusions: Timing Notch pathway inhibition in human retinal organoids to align with progenitor competency stages can yield a homogenous population of early cone or rod photoreceptors. Future work will focus on the effects of Notch inhibition on other retinal cells such as retinal ganglion cells and bipolar cells.

ABSTRACT BODY:

Purpose: Biological processes are imperfect and errors in trafficking to the outer segment (OS) of photoreceptors can result in the entry of inner segment proteins into the OS. The correction of such errors has been illuminated by studies of Bardet-Biedl Syndrome (BBS), a mendelian disorder whose cardinal features include retinal degeneration. The BBSome, a complex of BBS proteins, ferries membrane proteins out of cilia and retinal degeneration in BBS is likely caused by defects in the removal of mistargeted proteins from the OS, which is a specialized cilium. To better understand the pathological imbalances that leads to photoreceptor death in BBS, we sought to define the characteristics of proteins that are removed from the OS by the BBSome.

Methods: Past work in cultured cells has shown that ubiquitin (Ub) chains linked at lysine 63 (K63) mark cargoes for BBSome-mediated exit. We stained retinal sections of Bbs4 knockout mice at P15 with pan-Ub and linkage-specific probes. We next biochemically isolated the ubiquitinated proteins that accumulate in $Bbs4^{-/-}$ OSs using Tandem Ubiquitin Binding Entities (TUBEs). Experimental replicates and quantitative mass spectrometry enabled a statistically robust identification of BBSome cargoes in photoreceptors.

Results: Ubiquitin levels in the OS of $Bbs4^{-/-}$ mice are considerably elevated compared to control mice. Specifically, K63Ub chains accumulate in $Bbs4^{-/-}$ OS. Mass spectrometry analyses of K63Ub-associated proteins found 49 proteins statistically enriched ($p < 0.05$) by 1.5-fold in $Bbs4^{-/-}$ OS compared to wildtype OS while only 10 proteins were depleted. The vast majority of proteins linked to K63Ub that accumulate in $Bbs4^{-/-}$ OS are membrane proteins that are known to localize to the inner segment, to synaptic vesicles, or to the synaptic terminal. The identification of Syntaxin 3, a synaptic protein known to mislocalize to the OS in Bbs knockout mice, in this dataset directly validates our approach. The preliminary characterization of hits from our data set suggests the existence of a novel class of BBSome cargoes that may be subject to quality control.

Conclusions: The analysis of our mass spectrometry data set shows that K63Ub chains mark unwanted proteins for clearance from the OS by the BBSome. Our study generalizes the function of BBSome in the clearance of unwanted proteins from the OS and suggests the existence of quality control mechanisms that maintain the proteome of photoreceptor OS.

TITLE: In vivo Characterization of Corneal Shear Modulus Under Localized Cross-linking Using Confocal Air-coupled Optical Coherence Elastography

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Larin, F. Zvietcovich, A. Nair, M. Singh, S. Aglyamov, M.D. Twa, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Kirill Larin: Commercial Relationship: Code N (No Commercial Relationship) | Fernando Zvietcovich: Commercial Relationship: Code N (No Commercial Relationship) | Achuth Nair: Commercial Relationship: Code N (No Commercial Relationship) | Manmohan Singh: Commercial Relationship: Code N (No Commercial Relationship) | Salavat Aglyamov: Commercial Relationship: Code N (No Commercial Relationship) | Michael Twa: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recently, the riboflavin/UV-A collagen cross-linking (UV-CXL) clinical technique to treat corneal keratoconus has been applied locally in the cornea for patient-specific treatment. We hypothesize that a confocal air-coupled ultrasonic optical coherence elastography (ACUS-OCE) system can detect local changes of corneal elasticity in vivo under localized and global UV-CXL in rabbits.

Methods: ACUS-OCE measurements were made in four Dutch-Belted rabbits (n = 8 corneas) in the following protocol: (1) the left cornea was measured before (untreated: UT) and after half-treated (HT) UV-CXL; and (2) the right cornea was measured before and after full-treated (FT) UV-CXL. The ACUS-OCE setup includes a spectral-domain optical coherence tomography system coaligned with an air-coupled 1 MHz ultrasonic transducer that produced mechanical excitation (Lamb waves) at the apex of the corneas. Corneal thickness and Lamb wave speed were measured along four meridians: superior, inferior, nasal, and temporal. Finally, a modified Rayleigh-Lamb equation was used to convert wave speed into shear modulus.

Results: Lamb wave speed maps (Fig. 1a) along the inferior-superior direction are shown for the UT, HF, and FT corneas with UV-CXL. The inferior meridian (i.e., UV-CXL treated) in the HT cornea case was stiffer (~7.14 m/s) than its superior (untreated) meridian (~5.88 m/s). Moreover, the speed map for the FT case was symmetric and showed a marked speed elevation (~7.66 m/s) compared to the UT case (~5.31 m/s). There was a significant increase in the shear modulus in the inferior meridian of the left HT corneas ($p < .001$) after localized UV-CXL (Fig. 1b). Similarly, for the right FT corneas, there is a significant increase in shear modulus ($p < .001$) in all meridians after full UV-CXL.

Conclusions: In this work, we have demonstrated that ACUS-OCE can detect localized untreated and UV-CXL treated regions in the same cornea in vivo. This technology shows great potential for the monitoring and customization of patient-specific UV-CXL treatment.

ABSTRACT BODY:

Purpose:

To determine the prevalence of ocular findings during inpatient consultations for suspected neonatal Toxoplasmosis, Other, Rubella, Cytomegalovirus, and Herpesvirus (TORCH) infections. It is hypothesized that the prevalence of positive inpatient ocular examinations for TORCH rule out is low using current screening recommendations.

Methods: A retrospective chart review of neonates who received inpatient dilated ophthalmic exams for suspected TORCH infections while in the neonatal intensive care unit between May 2015 and October 2020 at a single, tertiary, safety-net institution. Birth weight, gestational age, reason for ophthalmology consultation, and associated ocular findings were recorded.

Results: he medical records of 84 patients were evaluated. The reasons for consultation included Small for Gestational Age (SGA, 40%), Intrauterine Growth Restriction (IUGR, 14%), Microcephaly (8%), Hypotonia (6%), Dysmorphic Features (3.5%), Maternal History of TORCH Infection in Previous Pregnancy (3.5%), and Conjunctivitis (3.5%). None of the patients had ocular examination findings consistent with congenital TORCH infection. The most common ocular finding was retinal hemorrhages (12%), however this is likely a consequence of birth trauma. One patient had positive urine IgM for CMV however no ocular findings. Other rare findings include Peters Anomaly, Primary Hyperplastic Persistent Vitreous, and Dacryocystocele

Conclusions: There was a surprisingly low prevalence of ocular findings in neonates receiving inpatient ocular examination for suspected congenital TORCH infections, despite a patient population that is reported to be at a higher risk of infection. The low diagnostic yield may be explained by the lack of a consensus recommendation for which patients with TORCH rule out would benefit from an urgent inpatient examination. It is likely more cost effective to reserve these examinations for an outpatient basis until clearer indications are defined. White we cannot provide specific criteria for examination based on our results, our study does suggest that inpatient neonatal ophthalmic examinations for TORCH rule out are not indicated solely for isolated cases of SGA or IUGR.

Commercial Relationships Disclosure: Darren Schuman: Commercial Relationship: Code N (No Commercial Relationship) | Aleksander Grimsrud: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Saban: Commercial Relationship(s);Code C (Consultant/Contractor):Novartis, Roche | William Stamer: Commercial Relationship: Code N (No Commercial Relationship) | Katy Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intracameral injections are an effective delivery route to tissues in the conventional outflow tract. One consequence of intracameral injection is a full-thickness corneal puncture and subsequent inflammatory response. This study assesses macrophage number and distribution in the conventional outflow tract after intracameral injection.

Methods: Intracameral injections were performed by a single puncture using beveled glass microneedles. C57Bl/6 mice, aged 3-5 months, received unilateral intracameral injection of 2µl of PBS with the contralateral eyes serving as untreated controls (n=3). In a separate cohort, mice underwent unilateral transcorneal needle puncture to one-half anterior chamber depth (without injection) with untreated contralateral eyes (n=2). Intraocular pressure (IOP) was monitored at baseline and daily after treatment. Mice were sacrificed and eyes enucleated 3 days post-treatment. Eyes were fixed and immunostained to identify macrophages in the conventional outflow tract. Anterior segment whole mounts were imaged by confocal microscopy, and macrophages were quantified from 5-6 non-consecutive 40X magnification images per eye. Statistical analysis was performed by one-way ANOVA and post hoc tests with $p < 0.05$ considered significant.

Results: At 3 days post-treatment, macrophage numbers increased in PBS injected and needle puncture eyes in the trabecular meshwork (TM) (53% with $p < 0.002$ and 40% with $p < 0.03$, respectively) and around distal vessels (DVs) (47% with $p < 0.0001$ and 60% with $p < 0.0001$, respectively) compared with untreated eyes. The number of macrophages in Schlemm's canal (SC) was unchanged with PBS injection or needle puncture ($p = 0.23$) compared with control eyes. There were no significant differences in IOP from baseline in sham injection, needle puncture and untreated groups ($p = 0.25, 0.25, 0.99$, respectively).

Conclusions: Intracameral injection of PBS results in an increased number of macrophages in TM and DVs but not SC, and our results suggest that this effect is due to needle puncture injury.

TITLE: Effectiveness of TearCare System in Improvement Dry Eye Disease Symptoms in Meibomian Gland Dysfunction

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Bloomenstein, Schwartz Laser Eye Center, Scottsdale, Arizona, UNITED STATES|J. Loh, Loh Ophthalmology Associates, Miami, Florida, UNITED STATES|K. Dhamdhere, Sight Sciences Inc, Menlo Park, California, UNITED STATES|

Commercial Relationships Disclosure: Marc Bloomenstein: Commercial Relationship(s);Code C (Consultant/Contractor):SIGHT SCIENCES | Jennifer Loh: Commercial Relationship(s);Code C (Consultant/Contractor):SIGHT SCIENCES | Kavita Dhamdhere: Commercial Relationship(s);Code E (Employment):SIGHT SCIENCES

ABSTRACT BODY:

Purpose: To demonstrate the superiority of the TearCare system in improvement of dry eye disease (DED) symptoms associated with meibomian gland dysfunction (MGD) compared to LipiFlow.

Methods: In this multi-center, masked, randomized-controlled trial, 235 subjects received a single TearCare treatment (n=115) or a single LipiFlow treatment (n=120) and were followed for 1-month post-treatment. DED symptoms were assessed using the Ocular Surface Disease Index (OSDI) Symptom Assessment in Dry Eye (SANDE), and eye dryness (ED) questionnaires at baseline and at 1-month. Subgroup analysis was conducted on subjects with less severe and more severe gland obstruction determined by baseline meibomian gland secretion score (MGSS).

Results: TearCare group and LipiFlow group had similar baseline mean OSDI (51.7 ± 14.79 and 51.7 ± 15.27). The reduction from baseline OSDI was 29.1 ± 1.62 for TearCare and 24.4 ± 1.59 for LipiFlow. The reduction in OSDI achieved with TearCare was significantly greater compared with LipiFlow (29.1 ± 1.62 vs 24.4 ± 1.59, pANCOVA = 0.04). Furthermore, subjects with more severe MGD (MGSS <7) achieved greater symptom-relief with TearCare compared to LipiFlow as shown in OSDI Section A (ocular symptoms), Section B (vision-related functions) and SANDE, $p_{ANCOVA} < 0.05$ for all comparisons.

Conclusions: TearCare provides significant DED symptom relief at 1-month after a single treatment. Outcomes were consistent in OSDI, SANDE, and ED assessments. In subjects with more severe gland dysfunction, TearCare performed significantly better than LipiFlow in improving quality of vision and overall DED symptom frequency determined by OSDI and SANDE.

TITLE: MEK inhibition reduces expression of transcription factor early growth response-1 (EGR1) in BRAF mutant and BRAF wild type melanoma

SESSION TITLE: Tumor - Diagnosis, prognosis, and molecular mechanism

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Andrews-Pfannkoch, D.R. Miley, S. Adams, A.D. Marmorstein, L.A. Dalvin, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|J.S. Pulido, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Cynthia Andrews-Pfannkoch: Commercial Relationship: Code N (No Commercial Relationship) | David Miley: Commercial Relationship: Code N (No Commercial Relationship) | Jose Pulido: Commercial Relationship: Code N (No Commercial Relationship) | Samantha Adams: Commercial Relationship: Code N (No Commercial Relationship) | Alan Marmorstein: Commercial Relationship: Code N (No Commercial Relationship) | Lauren Dalvin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the effects of mitogen activated protein kinase inhibitor (MEKi) treatment on EGR1 expression in BRAF mutant and wild type melanoma in cell culture.

Methods: We used three cell lines to investigate the response of EGR1, a transcription factor, to MEK inhibition. Two cell lines were derived from cutaneous melanoma, MEL888 and MEL624, and harbored the same BRAF mutant, Val600Glu (V600E). YUARGE 13-3064 was generated from a conjunctival melanoma neck lymph node metastasis and was BRAF wild type. After plating and overnight incubation, cells were treated daily for 72 hours with the MEK inhibitor trametinib at 18 nM concentration compared to DMSO vehicle control. At 72 hours, viability was measured using PrestoBlue™. qPCR and simple western assays were used to evaluate changes in EGR1 expression and a panel of genes associated with EGR1 and the MEK pathway. Targeted knockdown of EGR1 was performed to determine whether the observations in the MEK treated cells were a direct result of EGR1 knockdown.

Results: In MEL888, MEL624, and YUARGE 13-3064, treatment with the MEKi trametinib reduced viability and resulted in reduced EGR1 expression at the RNA ($p<0.001$, $p<0.001$, and $p=0.04$, respectively) and protein level ($p=0.03$, $p=0.03$, and $p=0.007$, respectively). Targeted EGR1 knockdown resulted in similar reduction in viability for BRAF mutant melanoma MEL888 compared with trametinib treatment.

Conclusions: MEKi treatment of BRAF mutant and BRAF wild type melanoma resulted in knockdown of EGR1 gene and protein expression in cell culture. Direct EGR1 knockdown resulted in reduced viability for BRAF mutant melanoma, suggesting a key role for EGR1 in the anti-cancer effects of MEKi for melanoma treatment.

Commercial Relationships Disclosure: Yurico Lopez: Commercial Relationship: Code N (No Commercial Relationship) | Jesus Guerrero: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Ramírez-Miranda: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas-Perez: Commercial Relationship: Code N (No Commercial Relationship) | Víctor Bautista- de Lucio: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Collagen crosslinking (CXL) is a proven effective treatment for halting the progression of keratoconus, with a low rate of complications including infection. To recognize risk factors is fundamental. We describe infectious keratitis prevalence and findings after accelerated (Epi-Off) and transepithelial (Epi-On) CXL in a third-level center.

Methods: Descriptive case series of patients who were treated with Epi-Off or Epi-On CXL for progressive keratoconus. We retrospectively reviewed all clinical records for a period of 10 years (2009-2018) of patients who underwent CXL for keratoconus. Keratitis patients were noted and analyzed. Based on clinical findings, they were classified either as sterile or infectious. Microbial cultures and antibiotic susceptibility were recorded when available. We recorded the following features: common risk factors, treatment regimen, detected microorganisms, antibiotic susceptibility, and clinical outcomes.

Results: From 1082 eyes reviewed, a total of 7 eyes developed keratitis (0.64%). Four of the seven cases presented as infectious keratitis (57.14%) and three as sterile keratitis (42.85%). Epi-On was performed in corneas with thinnest corneal point less than 380 um. Two cases developed keratitis in this group (28.57%). The mean time of presentation was 10.8 days postoperatively. The most common pathogen was Staphylococcus aureus (50%) and Staphylococcus epidermidis (75%). One case reported Pseudomonas mendocina culture growth. Preoperative mean best corrected visual acuity (BCVA) was 0.42 (logMAR), mean BCVA at resolution was 0.65 (logMAR). Most common posterior complications were corneal leucomas (71.4%). The use of steroids and soft bandage contact lenses in the immediate postoperative period were reported in 100% of the patients. Five cases were covered with antibiotic therapy in this period (tobramycin 42.85%, ciprofloxacin 14.2%, moxifloxacin 14.2%). History of atopic disease was present in 85.71% of all the cases.

Conclusions: The overall frequency of infectious keratitis after CXL remains low, but the implications can be deleterious. History of atopia could be associated with disturbance of the immunological barriers, predisposing to keratitis. The importance of judicious use of steroids, promptly identification of the condition and a cultured directed antimicrobial therapy when possible, as well as more frecuent check up visits may be highly valuable in these patients.

TITLE: Intrinsic signal optoretinography of dark adaptation abnormality due to rod degeneration

SESSION TITLE: Retinal Degeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Ding, T. Kim, X. Yao, Biomedical Engineering, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Jie Ding: Commercial Relationship: Code N (No Commercial Relationship) | Tae-Hoon Kim: Commercial Relationship: Code N (No Commercial Relationship) | Xincheng Yao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study is to demonstrate optoretinography of dark adaptation abnormality due to rod dysfunction in the retinal degeneration 10 (rd10) mouse model.

Methods: Six WT C57BL/6J and six rd10 mice at postnatal 14 days were used for this study. Optical coherence tomography (OCT) was employed for depth resolved morphological characterization of retinal layers. Time-lapse OCT measurement was used for intrinsic signal optoretinography of dark adaptation. Retinal B-scans were acquired in light condition and during 30 minutes of dark adaptation, with 5 min interval.

Results: Figure 1 shows comparative OCT imaging of the retina under light and dark-adapted conditions, revealing differences primarily within the outer retina part. Further analysis shows that the peak OCT intensity value of inner segment ellipsoid (ISe) band decreased, and the distance between external limiting membrane (ELM) and retinal pigment epithelium (RPE) reduced during the dark adaptation, compared to light condition. It was observed that the relative ISe intensity change was faster and larger in rd10, compared to WT. After 5 min, the relative ISe intensity value has significantly decreased in rd10 compared to the baseline ($p < 0.0001$); while significant ISe intensity decrease in WT was observed after 15 min ($p < 0.05$). Furthermore, the ISe intensity peak is split into a1 (left slope) and a2 (right slope). ISe band width has slightly decreased, while the intensity value of a1 both in WT and rd10 significantly dropped (WT $P<0.001$, Rd10 $P<0.01$, compared to light condition) and a2 also shown overall decrease.

Conclusions: In this study, we found that rd10 retina manifest abnormal outer retinal changes during dark adaptation. During dark adaptation, ISe band thickness was reduced in rd10, and peak intensity rapidly decreased compared to WT group.

ABSTRACT BODY:

Purpose: To compare changes in retinal layers and microvasculature in diabetic retinopathy (DR) patients after bevacizumab therapy and panretinal photocoagulation (PRP)

Methods: This prospective study divided patients into two groups: patients treated with bevacizumab and those treated with PRP. Patients visited our retinal clinic at 1, 3, and 6 months after treatment. Retinal layer thickness and vessel density (VD) using optical coherence tomography angiography were analyzed

Results: 37 eyes in the bevacizumab group and 36 eyes in the PRP group were enrolled. In the bevacizumab group, the parafoveal RNFL, GCL, and IPL thicknesses significantly decreased ($P < 0.001$, $P = 0.013$, and $P = 0.017$, respectively), whereas the thicknesses in the PRP group showed an increasing tendency over time ($P = 0.087$, $P = 0.005$, and $P = 0.003$, respectively). The VD of the superficial capillary plexus (SCP) and deep capillary plexus (DCP) in the bevacizumab group did not show significant changes, whereas the VD in the PRP group significantly increased over time (both $P < 0.001$). Additionally, RNFL ($P = 0.001$) and GCL thicknesses ($P = 0.035$) were significant factors affecting changes in BCVA, whereas the VDs of SCP and DCP did not.

Conclusions: Patients who received bevacizumab therapy did not show a significant change in macular VD, whereas the VD of patients after PRP significantly increased after treatment. The increased macular VD in patients after PRP would be associated with the increased inner retinal layer thickness after treatment, which was significantly related to the impairment in visual acuity.

ABSTRACT BODY:

Purpose: To compare and determine the best intraocular lens formula in eyes greater than 25mm with normal and keratometries greater than 45D.

Methods: Retrospective comparative study. 119 eyes with axial length 25mm were included and divided into two groups: Ksteep (45D) and Kreg (<45D). Refractive error (RE) was calculated with 10 calculation formulas. Mean absolute error (MAE) and median absolute error (MedAE) of RE were compared. The percentage of eyes was obtained at ±0.50, ±1.00 and ±2.00 diopters, as well as the OR of achieving a refraction at ±0.50D.

Results: For the Ksteep group, the lowest MAE was from Panacea, Kane and Barret U2. The lowest MedAE was Ladas, Panacea and SRKII with the highest percentage in ±0.50D of Panacea and Kane. For the Kreg group the lowest MAE was from Kane and Hill-BRF. The lowest percentage at ±0.50D of Kane, Barret U2 and Haigis. All the formulas except Hill-BRF and Barret U2 presented statistically significant difference in MedAE between both groups.

Conclusions: Kane and Panacea had the best results for long eyes with keratometries greater than 45D. For long eyes with normal keratometries the best formulas were Hill-BRF and Barret U2. The latter can be used in long eyes regardless of keratometry.

ABSTRACT BODY:

Purpose: Despite quantitative diabetic macular ischemia (DMI) assessment using optical coherence tomography-angiography (OCT-A) is gradually recognized, most of OCT-A studies only focus on using small-of-view with high-resolution (HR) scanning protocol to ensure the reliability of measurement. We aim to develop a DL network to reconstruct 6mm×6mm OCT-A images with image-quality enhancement to tackle the issue of “resolution trade-off” between field-of-view, image-quality and scanning time.

Methods: A novel texture-transformer-based DL network was built for reconstruction task for 6mm×6mm (320A-scan/320B-scan) fovea-center OCT-A images (Fig 1) acquired from a swept-source OCT (Triton DRI-OCT, Topcon, Inc., Japan). 296 eyes from 158 individuals with diabetes were used for training and primary validation (8:2) with each eye consists of one 3mmx3mm and one 6mm×6mm fovea-center OCT-A images. Structural similarity index measure (SSIM) and peak signal-to-noise ratio (PSNR) were used to compare the image-quality before and after reconstruction. To test the relationship between OCT-A metrics and diabetic retinopathy (DR) severity on the reconstructed images. We used a non-overlapping dataset (no DR: 22; mild DR:20; moderate DR:18; severe DR or proliferative DR:18) with each eye consists of 5 3mmx3mm (320A-scan/320B-scan, 1 fovea-center and 4 at parafoveal regions) and 1 6mm×6mm (320A-scan/320B-scan, fovea-center) OCT- A images. The 5 3mmx3mm OCTA images were then stitched as montage to provide a HR 6mm×6mm image serving as the “ground-truth” to the reconstructed images.

Results: After image reconstruction, better visibility of retinal capillaries are appreciated (Fig 2). The SSIM ($SSIM_{original}$ = 0.670 vs. $SSIM_{reconstructed}$ = 0.500, $p<0.001$) and PSNR ($PSNR_{original}$=19.71 vs. $PSNR_{reconstructed}$ =17.41, $p< 0.001$) of the reconstructed images was significantly higher than that of the original images. In the non-overlapping dataset, we measured foveal avascular zone (FAZ) area, FAZ circularity, vessel density on both the ground-truth and reconstructed images. We found that the associations of the OCT-A metrics with DR severity between “ground-truth” and reconstructed images were large identical (i.e. similar R^2 values).

Conclusions: The proposed DL network can enhance the image-quality among OCT-A images with lower resolution and maintain the accuracy of quantitative OCT-A measurements.

ABSTRACT BODY:

Purpose: To evaluate nerve fiber layer (NFL) reflectance for glaucoma diagnosis using a large dataset.

Methods: Participants were imaged with 4.9mm ONH scans using spectral-domain optical coherence tomography (OCT). The NFL reflectance map was reconstructed from 13 concentric rings of optic nerve head(ONH) scan, then processed by an azimuthal filter to reduce directional reflectance bias due to variation of beam incidence angle. The peripapillary thickness and reflectance maps were both divided into 96 superpixels. Low-reflectance and low-thickness superpixels were defined as values below the 5th percentile normative reference for that location. Focal reflectance loss was measured by summing loss, relative to the normal reference average, in low-reflectance superpixels. Focal thickness loss was calculated in a similar fashion. The area under receiving characteristic curve (AROC) was used to assess diagnostic accuracy.

Results: Fifty-three normal, 196 pre-perimetric, 132 early perimetric, and 59 moderate and advanced perimetric glaucoma participants were included from the Advanced Imaging for Glaucoma Study. Sixty-seven percent of glaucomatous reflectance maps showed characteristic contiguous wedge or diffuse defects. Focal NFL reflectance loss had significantly higher diagnostic accuracy than the best NFL thickness parameters (both map-based and profile-based): AROC 0.80 v. 0.75 ($p<0.004$) for distinguishing glaucoma eyes from healthy control eyes. The diagnostic sensitivity was also significantly higher at both 99% specificity operating points.

Conclusions: Focal NFL reflectance loss improved glaucoma diagnostic accuracy compared to the standard NFL thickness parameters.

ABSTRACT BODY:

Purpose: Acute posterior multifocal placoid pigment epitheliopathy (APMPPE) is a generally self-limited disease with a good prognosis and resolution of symptoms between 4 weeks and 6 months. Retinal imaging is used to establish the diagnosis; however, the resolution of routine diagnostic imaging to assess changes at the photoreceptor level is limited. Here we explored outer cellular retinal structure of APMPPE lesions in a patient 4 years after initial presentation and 8 months after recurrent scotoma symptoms in the same region as her initial APMPPE scotomas a few days after her first COVID-19 vaccine.

Methods: The subject underwent a complete eye exam and high resolution imaging. Outer retinal structure was assessed using spectral domain optical coherence tomography (SD-OCT), and the photoreceptor mosaic was imaged using both confocal and split detection adaptive optics scanning light ophthalmoscopy (AOSLO).

Results: SD-OCT identified a subtly irregular ellipsoid zone (EZ) band in the area of a previous APMPPE lesion, improved from initial presentation and initial visit after reactivation. Confocal AOSLO (Figure A) revealed an abrupt transition from dense regularly spaced cones to a disrupted photoreceptor mosaic. However, confocal AOSLO signal can be difficult to interpret in the presence of debris or non-waveguiding cones. Split detection AOSLO (Figure B) highlights cone inner segments providing a clearer view of cone distribution even in the absence of waveguiding and revealed reduced photoreceptor density in disrupted areas (Figure A and B '*').

Conclusions: COVID-19 vaccination may induce reactivation of APMPPE symptoms. Despite improved EZ band structure by SD-OCT in the areas of previous APMPPE lesions, AOSLO revealed several focal areas of persistent subclinical photoreceptor loss. Split detection AOSLO allows for more precise assessment of photoreceptor structure and highlights the variability in inner segment changes throughout retina lesions. This demonstrates the potential utility of split-detector AOSLO for assessment of photoreceptor structure alterations in retinal uveitic diseases such as APMPPE.

ABSTRACT BODY:

Purpose: Punctate inner choroidopathy (PIC) and multifocal choroiditis (MFC) are two white dot syndromes that share common clinical features such as choroidal neovascularization (CNVM), cystoid macular edema (CME), intraocular inflammation, and retinal atrophy. This study investigates phenotypic differences between these two inflammatory diseases utilizing fluorescence lifetime imaging ophthalmoscopy (FLIO).

Methods: 8 eyes of 8 patients with PIC and 6 eyes of 6 patients with MFC (mean age 40 ± 18 years) and 14 age-matched healthy subjects were investigated in this study. FLIO images of a 30° retinal field at the foveal center were acquired using a prototype Heidelberg Engineering Spectralis-based FLIO. In all patients, FLIO lifetimes were recorded in short (498-560 nm, SSC) and long (560-720 nm, LSC) spectral wavelength channels, with mean autofluorescence lifetimes (tm) calculated and analyzed. In addition, FLIO lifetimes from PIC and MFC-specific lesions were obtained and compared in both spectral channels.

Results: FLIO can discriminate between PIC and MFC based on phenotypic differences in FLIO lifetimes from both spectral channels. While MFC lesions have consistently prolonged of lifetimes in both channels, PIC lesions show heterogeneity of long and short lifetimes in the SSC and LSC, respectively. Some PIC lesions with long FLIO lifetimes in the SSC emit short FLIO lifetimes in the LSC. Collectively, FLIO lifetimes are prolonged in MFC and PIC compared to age-matched controls in the outer ring of the posterior pole in the LSC (240 ps versus 194 ps, $p<0.05$).

Conclusions: FLIO proves to be a promising imaging modality that offers a possibility to differentiate between PIC and MFC. The lifetime heterogeneity seen in PIC and significantly prolonged lesion lifetimes of MFC patients may provide additional diagnostic tools as well as insight into disease-specific mechanisms, activity, and progression.

ABSTRACT BODY:

Purpose: Photoreceptors are metabolically active retinal cells. Disturbance in photoreceptor metabolism leads to neuronal degeneration associated with a broad range of diseases such as age-related macular degeneration, and diabetic retinopathy. Understanding the changes in this process is critical for unraveling disease mechanisms and developing new treatments. The goal of this study is to develop an accurate and reliable approach for the measurement of energy metabolism in isolated mouse retinal photoreceptors.

Methods: Rod photoreceptor cells from dark-adapted mouse retinas were isolated using enzymatic digestion and mechanical dissociation. Cell viability was evaluated using Trypan blue and live-dead assays. Neuronal population and preservation of cell structure were examined by immunofluorescence staining. Cellular bioenergetics were measured by extracellular flux analysis using a Seahorse extracellular flux analyzer. To maintain a high number of metabolically active cells, dark conditions were used throughout the process of dissociation, cell seeding, and metabolic analysis.

Results: Successful isolation of retinal photoreceptors was achieved using as few as one single mouse retina. Immunostaining for multiple retinal neuronal markers revealed that 90% of the dissociated cell population were rod photoreceptors. The majority of photoreceptor cells preserved an intact structure and 93% of them were viable. Reproducible functional data were obtained in oxygen consumption rate (OCR) for mitochondrial respiration and extracellular acidification rate (ECAR) for glycolysis with adjustment of cell densities and titration of substrate concentrations. Compared to analysis using retinal explants, dissociated retinal photoreceptors demonstrated an enhanced response to inhibitors for mitochondrial respiration in metabolic assays.

Conclusions: Our study provided a novel approach for reproducible and accurate measurement of energy metabolism in dissociated mouse retinal rod photoreceptors, which may have a broad application in future studies on retinal degenerative disease.

ABSTRACT BODY:

Purpose: Despite growing literature looking at factors that contribute to the closure of full-thickness macular holes, there are still gaps in our knowledge. This study sought to examine the role of preoperative and intraoperative factors in predicting anatomic and visual success of vitrectomy for full-thickness macular holes.

Methods: A retrospective chart review of cases in year 2018-2019 was conducted at the University of Wisconsin. Inclusion criteria included vitrectomy for macular hole and pre- and post-operative imaging. Successful closure was defined as the absence of a full-thickness disruption by imaging. Final statistical analyses are currently underway. Data will be summarized using the median and inter quartile range (IQR; span from 25^{th} to 75^{th} percentile capturing central 50% of the sample) for continuous features or with frequencies and percentages for categorical factors. Risk factors associated with hole closure will be compared between groups using either rank-sum procedures or Fisher's exact tests. Analyses will be performed using R (ver. 4.0.3).

Results: There were 138 subjects who met inclusion criteria and had vitrectomy for macular hole. One had a traumatic injury and was especially young (< 15 years old) at the time of repair; all others were between 42–87 years at time of surgery, with the mean age of 71.5. 69.5% of patients were female. Internal limiting membrane was peeled in all cases. Hole closure was successful for 126 subjects (90.5%); 120 (95%) of these had single surgery success. Age, lens status, prior hole repair, and chronicity (present > 1 year), pathologic myopia or staphyloma were included in data collection, among several other variables of interest. 6 (50%) of the unsuccessful surgeries were highly myopic patients and 11 of the total 17 (64.7%) highly myopic patients achieved successful closure. Mean minimum hole diameter (MHD) was 316.2 uM. A larger mean MHD was found among those who had an unsuccessful repair (598.2 uM). Mean preoperative logMAR visual acuity was 0.81 with mean improvement to 0.52 postoperatively.

Conclusions: The study suggests that factors such as being highly myopic and large MHD may portend a decreased likelihood of a successful macular hole surgery, although final statistical analyses are pending.

Commercial Relationships Disclosure: Aniruddh Srinivasan: Commercial Relationship: Code N (No Commercial Relationship) | Pawan Shahi: Commercial Relationship: Code N (No Commercial Relationship) | Sehrish Afsheen: Commercial Relationship: Code N (No Commercial Relationship) | Bikash Pattnaik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The effect of KCNQ-targeting drugs on the visual light response (VLR) is unknown. Previous studies have demonstrated the expression of these channels in the retina and retinal pigment epithelium (RPE). Patients note persistent visual disturbances while using the KCNQ-activating anti-epileptic drug Retigabine. Given that KCNQ subunits are also expressed in the retina, we sought to identify how KCNQ modulators alter rodent retinal function.

Methods: VLR was assessed with ex-vivo or full field electroretinograms (exERG, ffERG). For exERGs, retinae were removed from freshly enucleated mice eyes and stimulated using OcuScience's ex-vivo ERG (custom protocol). Baselines were recorded in Ames medium. Retinae were incubated in 10 μM Zinc Pyrithione (ZP), 10 μM RL-648_81 (RL), 10 μM XE-991 (XE), 50 μM L-AP-4 (positive), 0.5% DMSO or 0.1% PBS treated Ames for 20 minutes. Another exERG was then taken, and a final recording after a 20-minute Ames wash. ffERGs were performed on the Espion-E3 system using the ISCEV protocol to assess a and b-waves and a custom c-wave protocol. Recordings consisted of a baseline, ffERG 15 minutes after treatment, and a follow-up after 3 days. Drugs were injected intravitreally for final vitreal concentrations given above. Two-tailed Student's t-test was used for data analysis.

Results: ExERGs revealed b-wave amplitude reductions in ZP treated retina (89 ± 22 μV) compared to baseline, (247 ± 38 μV, $p = 0.01$), which persisted post-wash. b-wave implicit time (IT) increased in ZP treated groups (116 ± 10 ms) relative to baseline (78 ± 6 ms, $p = 0.009$). Amplitude decrease was not observed with concurrent XE and ZP treatment, but IT was still delayed.

For ffERGs, b-wave and c-wave amplitude of ZP treated eyes decreased (233 ± 24, 161 ± 61 μV) compared to baseline (408 ± 31, 523 ± 37 μV, $p = 0.001$, 0.0008). b-wave IT decreased after ZP treatment (66 ± 13 ms) relative to baseline (32 ± 1 ms, $p = 0.03$). Interestingly, RL treatment increased a-wave amplitude (178 ± 17 μV) above baseline (113 ± 19 μV, $p = 0.04$). All mice had normal follow-up ffERGs.

Conclusions: Our results show that KCNQ modulation may alter retinal function. However, differences between the RL and ZP responses suggest non-uniform expression of functional KCNQ subunits in the retina. Exploration of ocular KCNQ distribution and modulation in specific retinal circuits will further elucidate the role of KCNQ channels in VLR.

ABSTRACT BODY:

Purpose: To observe the influence of preoperative vancomycin exposure on cataract surgery outcomes.

Methods: A retrospective cohort study was performed using patients from a national database, TriNetX (Cambridge, MA, USA), which compiles patient data in healthcare records from several large healthcare organizations in the United States. Patients undergoing cataract surgery were identified by CPT code and placed into cohorts based on any history of vancomycin use within one year prior to surgery vs. no history of vancomycin within one year prior to surgery. Patients were matched for age, BMI, sex, hypertension, diabetes, chronic respiratory disease, heart failure, and nicotine dependence. Primary outcomes were: Vitreous Hemorrhage, Choroidal Hemorrhage, Retinal Detachment (RD) or Break, Iridocyclitis, Retinal Edema (RE), Cystoid Macular Degeneration (CMD), Macular Puckering (MP), Toxic Maculopathy, Ischemic Optic Neuropathy (ION), Glaucoma, Strabismus, Hemorrhage of Orbit, Corneal Edema (CE), Dry Eye Syndrome (DES), Central Retinal Vein Occlusion (CRVO), Central Retinal Artery Occlusion (CRAO), Vitreous Opacities, Ptosis, lens dislocation, Endophthalmitis, Retinal Vascular Occlusions (RVO). Outcomes were compared between cohorts after propensity score matching using logistic regression.

Results: 32,716 patients were included in the study, with 16,358 in both the vancomycin-receiving and non-vancomycin-receiving groups. Vancomycin use was associated with higher rates of RE (RR 1.24; 95% CI, 1.04-1.49), CMD (RR 1.23; 95% CI, 1.08-1.4), MP (RR 1.28; 95% CI, 1.1-1.48), ION (RR 2.17; 95% CI, 1.1-4.3), glaucoma (RR 1.23; 95% CI, 1.09-1.4), DES (RR 1.26; 95% CI, 1.14-1.39), ptosis (RR 1.27; 95% CI, 1.06-1.53), endophthalmitis (RR 2.02; 95% CI, 1.47-2.76). Vancomycin use was associated with fewer vitreous opacities (RR 0.77, 95% CI (0.64-0.93). There was no significant difference between rates of vitreous or choroidal hemorrhage, hemorrhage of orbit, RD or retinal break, iridocyclitis, toxic maculopathy, strabismus, CE, lens dislocation, or RVOs such as CRVO or CRAO.

Conclusions: Vancomycin use may be associated with postoperative complications after cataract surgery. Patients who received vancomycin within one year before cataract surgery were more likely to develop RE, CMD, MP, ION, glaucoma, DES, ptosis, and endophthalmitis. The risk of these complications should be considered and discussed when evaluating patients peri-operatively.

Commercial Relationships Disclosure: Yuhua Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Xiaolin Wang: Commercial Relationship: Code N (No Commercial Relationship) | Boyu Gu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the relationship among the velocity, cell flux, and cell lineal density of the erythrocytes in the human retinal capillaries.

Methods: We imaged the erythrocytes flowing in retinal capillaries of the human subjects in normal ocular and physical health, using a high-speed adaptive optics near-confocal ophthalmoscope at a frame rate of 800 Hz. We measured the erythrocyte velocity, lineal density (defined as the number of cells presenting within a certain length of the capillary), and cell flux (defined as the number of cells per second flowing through a capillary segment) within a cardiac cycle with custom software.

Results: In 29 macular capillaries of 7 eyes of 7 human subjects aged 20-29 years old, the linear density was 59.60 ± 10 cells/mm and cell flux was 60.16 ± 20.18 cells/s. In a single capillary, erythrocyte cell flux showed a distinctive fluctuation associated with the heartbeat, the lineal density of erythrocytes varied over time within a cardiac cycle, but the average lineal density over multiple cycles exhibited a fairly consistent distribution within a cardiac cycle under the normal cardiovascular and respiratory resting state (Figure).

Conclusions: The consistent erythrocyte lineal density over time in a retinal capillary disclosed the essential number of erythrocytes that are needed to provide a constant, uniform flux of oxygen to the local tissue thereby maintaining a normal retinal function. In vivo quantification of erythrocyte lineal density in human retinal capillaries under the natural rheological state may provide a potential useful biological index or a biomarker for assessing vascular function and pathophysiology.

ABSTRACT BODY:

Purpose: The presence of schisis cavities in the central retina has hampered safe and effective delivery of AAV-RS1 to XLRS patients. The novel AAV.SPR capsid laterally spreads well beyond the margins of the subretinal injection (SRI) bleb, providing a means to perform peripheral SRI (without detaching the fovea and avoiding schisis cavities) and effectively deliver RS1 to both the peripheral and central retina. The purpose of this study was to (1) evaluate the efficacy of AAV.SPR-hRS1 in Rs1 knock-out (RS1KO) mice and (2) compare the extent of central retina transduction mediated by AAV.SPR and AAV5 vectors encoding myc-tagged RS1 following peripheral SRI.

Methods: GFP, hRS1 or myc-RS1 were packaged into AAV.SPR and AAV5. RS1KO mice were treated via SRI with 3 different doses of vector, and retinal structure and function were assessed over 6 mo by OCT and ERG, respectively. Cynomolgus macaques were treated via SRI with AAV vectors expressing myc/hRS1 alone or both AAV-GFP and AAV-myc/hRS1. Vectors were delivered in either one or two extrafoveal blebs, and wide field color fundus, cSLO and OCT images were collected for up to 6 wk post-injection. Immunohistochemistry and biodistribution analysis were performed post mortem.

Results: Improvements in both retinal structure (resolution of schisis cavities), and function (scotopic and photopic b-waves) were observed in a dose-dependent manner, and hRS1 expression was observed in PR inner segments of RS1KO mice treated with AAV.SPR-hRS1. GFP and myc/RS1 expression was observed well beyond the bleb margins in NHPs treated with AAV.SPR (but not AAV5) vectors, including the majority of foveal cones, and myc/RS1 expression mimicked that of endogenous NHP RS1. Biodistribution of AAV.SPR compared favorably to AAV5.

Conclusions: A novel AAV vector has been developed for the treatment of XLRS. AAV.SPR delivered therapeutic levels of hRS1 to subretinally injected RS1KO mice, resulting in improvements in both retinal structure and function. In addition, AAV.SPR safely and efficiently mediated hRS1 expression in the central retina of primate eyes following peripheral subretinal injection. Contrary to previous vectors delivered intravitreally, SRI of AAV.SPR represents a safer (avoids surgical manipulation of schisised retina and fovea) and potentially more effective (promotes efficient transduction of photoreceptors) option for the treatment of XLRS.

ABSTRACT BODY:

Purpose: In advanced retinitis pigmentosa, severe photoreceptor degeneration occurs. Optogenetics therapy offers the potential for vision restoration in these patients by photosensitizing higher order neurons. Since this approach focuses on disease phenotype versus a specific genotype deficit, it is applicable to a wide patient population. Existing optogenetic tools utilize opsins that do not generate adequate electrical current in ambient light requiring an external device for stimulation. Further, evaluation of efficacy in such low-vision patients require development of novel endpoints.

Methods: Multi-Characteristic Opsin (MCO) is an engineered opsin that is activated at ambient light levels, thereby avoiding the need for an external amplifying device and associated phototoxicity. Through the delivery of opsin encoding genes, residual retinal neurons take on the photosensitizing function of the photoreceptors. Targeting bipolar cells with MCO allows potential for greater spatial resolution. AAV2 was used to deliver MCO in advanced retinitis pigmentosa subjects. Subjects received prophylactic oral steroids prior to a single intravitreal injection of AAV2-MCO (vMCO). Safety of different intravitreal vMCO doses is evaluated using OCT, slit lamp and indirect ophthalmoscopy. Novel end points such as Y-Mobility Test (YMT) and Low-Vision Multi-Parameter Test (LVMPT) utilizing multiple luminance levels are deployed to evaluate efficacy.

Results: Approximately 50% low-vision subjects at multiple centers passed the screening criterion requiring failing of the YMT at 1 lux. The three-dimensional shape recognition by LVMPT allowed measurement of accuracy in shape recognition at different light intensities. The two different vMCO doses are well tolerated with no reported serious adverse events. Ocular adverse events include inflammation and intraocular pressure rise in few subjects, controlled via medication without requiring any surgery.

Conclusions: The vMCO doses are well tolerated with no serious adverse events. The novel endpoint measurements in low-vision subjects in a randomized and masked manner provide opportunity to evaluate the efficacy of the optogenetic vMCO monotherapy in improving functional vision in advanced RP patients.

ABSTRACT BODY:

Purpose: To measure the levels of VEGF in aqueous of patients with exudative macular degeneration (eAMD) receiving intravitreal anti-VEGF agents and to explore whether this can be used to personalize treatment options for patients.

Methods: The study was approved by the local University IRB. Aqueous samples were collected at the time of paracentesis following each intravitreal injection of an anti-VEGF agent given serially every 4 – 6 weeks in patients with eAMD. These samples were immediately stored in -80^{0} C freezer. At the time of analysis, aqueous samples were thawed at room temperature and VEGF (pg/ml) levels were measured using human premixed multi-analyte kit and magnetic bead assay on Luminex MAGPIX analyzer (Austin, TX, USA).

Results: In 139 samples from 31 eyes, the average VEGF level from the first sample measured in each patient was 34.9 pg/ml. This decreased significantly to an average level of 6.8 pg/ml in the last sample measured from each patient after 2 – 10 injections (average 4.5 injections) of an anti-VEGF agent. The change in VEGF levels correlated with the presence of subretinal fluid on OCT.

Conclusions: Aqueous levels of VEGF can be easily measured at every injection in eAMD patients. Aqueous levels of VEGF were significantly reduced after treatment with anti-VEGF agents. With the ease of obtaining the aqueous sample and measuring the VEGF levels, this parameter maybe a useful parameter in the future, in addition to visual acuity and retinal thickness, to possibly personalize the treatment of eAMD patients.

ABSTRACT BODY:

Purpose: Glaucoma is one of the leading causes of irreversible blindness in the United States, affecting nearly 3 million. This number is expected to rise to 6.3 million by the year 2050. We performed a cross-sectional study investigating the interactions between Social Determinants of Health (SDOH), self-reported non-adherence, and Glaucoma Severity (GS) in vulnerable patients.

Methods: Participants that met inclusion criteria of confirmed clinical diagnosis of glaucoma, on medical therapy, at an academic medical center in Newark, NJ serving a widely underserved population (Median Income $20k) were randomly enrolled. All participants completed a structured survey in their preferred language (English or Spanish) consisting of demographic information, self-reported adherence and Short Assessment of Health Literacy (SAHL). Subjects unwilling to complete surveys were excluded. Objective data included Visual Field Mean Defect (MD). Survey scores were correlated with demographic and objective data. Participants were compared based on mild or severe glaucoma severity (MD <-12dB, MD >-12dB, respectively) and high or low health literacy (score: 15-18 and 0-14 correct, respectively). Continuous data was compared using analysis of variance (ANOVA) and t-tests.

Results: 61 participants met inclusion criteria, with a median age of 62 years. The majority of participants were female (65.5%), Black (48%), and had a low education (no diploma or high school only, 57.3%). Participants who classified as severe (N=25) more often reported having high school education or less (60%), greater difficulty accessing medication (60%), and lack of adherence (59%). Severe glaucoma was associated with low-health literacy($P<.05$). Participants lost to follow-up, 75% classified as having low health literacy and no education. The association between glaucomatous severity, education level, and health literacy level was significant ($p<.05$). Average mean defect was calculated for each demographic (Table 1).

Conclusions: Patients with vulnerable demographic risk-factors may have a higher burden of severe glaucoma and difficulty with adherence. This pilot study supports that various SDOH may predict GS and loss to follow-up. Further studies need to be conducted on larger populations to guide appropriate preventative intervention for identified patients.

ABSTRACT BODY:

Purpose: The shapes of phosphenes elicited by epiretinal prostheses have been shown to depend on stimulus parameters as well as the retinal location of the stimulating electrode. While previous studies have individually documented some of these effects, there is not yet a single model that can predict phosphene appearance across a wide range of electrical stimuli. To fill this gap, we conducted a meta-analysis across multiple modalities of patient data to comprehensively document and model the effects of stimulus amplitude, frequency, and pulse duration on phosphene appearance.

Methods: We first aggregated data from four psychophysical (phosphene drawings, size and brightness ratings) and one electrophysiological study (retinal ganglion cell activation maps) to investigate the effect of stimulus amplitude, frequency, and pulse duration on phosphene size, brightness, and streak length across 7 different Argus I/II users (Second Sight Medical Products) as well as 15 wild-type rat retinas. We then developed a simple phosphene model using a simulated map of retinal nerve fiber bundles combined with a few simple equations constrained by our combined dataset. We evaluated per subject how well the model predicted phosphene area, orientation, and ellipse major/minor axis length on held-out electrodes and compared the results to previous models.

Results: Phosphenes grew brighter ($r=0.64$, $p<0.01$), larger ($r=0.46$, $p<0.001$), and less elongated ($r=-0.14$, $p<0.05$) with increasing amplitude, grew brighter ($r=0.77$, $p<0.001$) with increasing frequency, and grew brighter ($r=0.85$, $p<0.001$), larger ($r=0.85$, $p<0.001$), and less elongated ($r=-0.84$, $p<0.001$) with increasing pulse duration (Table 1). When fit to data from individual patients, the model accurately predicted brightness as a function of amplitude ($R^2=0.91$) and frequency modulation ($R^2=0.97$) as well as size for amplitude ($R^2=0.97$). The model also generalized to brightness ratings from new subjects ($R^2=0.61$).

Conclusions: Through an analysis of psychophysical and electrophysiological data, we modeled the effects of various stimulus parameters on phosphene appearance in epiretinal prostheses. Overall this work is an important step towards predicting visual outcomes across a wide range of stimuli.

ABSTRACT BODY:

Purpose: VEGF plays a central role in the physiology of the eye as well as the pathology of AMD. Receptors for VEGF exist in the RPE, but their exact role in the physiology of the RPE is not well characterized. VEGFR1 is a member of the VEGF receptor family that can have contradictory effects on VEGF signaling. It can negatively regulate VEGF-mediated angiogenesis through sequestration of VEGF. At the same time, although it possesses weaker tyrosine kinase activity than VEGFR2, signaling through VEGFR1 has been found to be important in the mediation of inflammation. As inflammation of the RPE is a key component of AMD pathogenesis, we elected to more closely examine the localization of VEGFR1 in the RPE.

Methods: VEGFR1 expression was assessed in RPE cells of adult c57/bl6, cd1, and rd10 mice by immunostaining of RPE flat mounts and cryosections with two different antibodies against VEGFR1. In addition, we examined VEGFR1 expression in primary RPE cell culture from c57/bl6 mice retina. In some cases, we treated the RPE cells with VEGFR1 siRNA or shRNA to further validate VEGFR1 expression.

Results: We found VEGFR1 staining in c57/bl6 and cd1 RPE flat mounts across 3 time points (P30, P50, P70). In contrast, it was significantly reduced in rd10 RPE flat mounts checked at 3 time points (P30, P100 and P750). VEGFR1 staining could be cytoplasmic or nuclear. This was further examined in cryosections of wild type mouse eyes, where nuclear staining co-localized with immunostaining for Otx2, a transcription factor found in RPE nuclei. A blocking peptide eliminated this staining. RPE cells freshly isolated from c57/bl6 mice in primary culture also showed staining for VEGFR1 in the nucleus and cytoplasm, and these levels could be reduced after transfection of either VEGFR1 siRNA or a VEGFR1 miR30 shRNA construct. A scrambled shRNA construct that does not target VEGFR1 RNA did not show a reduction of VEGFR1.

Conclusions: VEGFR1 is expressed in the RPE of wild type mice, and can be found in both the nucleus and the cytoplasm. VEGFR1 is significantly reduced in the rd10 mouse model of retinal degeneration. The interesting pattern of VEGFR1 localization suggests the value of studying the role of VEGFR1 beyond its role in VEGF sequestration.

ABSTRACT BODY:

Purpose: Extracellular matrix (ECM) remodeling is a key factor in retinal development. Recent work suggests the ECM protein Cellular Communication Network Factor 2 (CCN2) regulates retinal progenitor cell survival, proliferation, and differentiation. We employed transcriptional profiling of murine embryonic retinas to test the hypothesis that CCN2 regulates the ECM in a cell type-dependent manner and mediates cell fate specification.

Methods: Germline CCN2 deletion was achieved using a $Ccn2^{fl/fl}$; CMV-Cre mouse model. Embryonic day (E)18 $CCN2^{-/-}$ and $CCN2^{+/+}$ littermate control retinas from both sexes were used for bulk RNA sequencing (RNA-seq) (n=3), RT-qPCR (n≥3), and single-cell (sc)RNA-seq (n=2). RNA-seq and scRNA-seq data were interrogated by Gene Set Enrichment Analysis (GSEA).

Results: In $CCN2^{-/-}$ retinas, GSEA of RNA-seq data revealed significant repression of the Core Matrisome gene set (p=0.017, q=0.20), representing the core components of the ECM proteome. New retinas were probed via RT-qPCR for a selection of Core Matrisome genes, which confirmed broad ECM repression. Subsequent scRNA-seq and GSEA were performed with new retinas. Each retinal cell type possessed a unique ECM expression signature, and Ccn2 was specifically expressed by retinal progenitor cells (RPCs). CCN2 deficiency repressed the structural ECM genes Col1a2 (-2.58-fold, p<0.01) and Col5a2 (-1.88-fold, p<0.001) specifically in RPCs. Damaged cells were approximately 3-fold more prevalent in $CCN2^{-/-}$ retinas compared to controls (17.6% vs. 5.76%), suggesting decreased viability following CCN2 deletion. Among retinal ganglion cells (RGCs), $CCN2^{-/-}$ retinas contained a greater proportion of immature RGCs compared to controls (71.2% vs 51.8%). Accordingly, RGCs from $CCN2^{-/-}$ retinas repressed a fetal RGC gene set (p<0.001, q<0.001) and upregulated a fetal RPC gene set (p<0.001, q<0.001). Finally, GSEA of scRNA-seq data revealed cell type-specific regulation of the Core Matrisome, which in $CCN2^{-/-}$ retinas was repressed in RPCs (p=0.017) yet upregulated in RGCs (p=0.021) and horizontal cells (p=0.016).

Conclusions: In the developing retina, CCN2 mediates pan-retinal ECM gene expression, yet differentially regulates the ECM in a cell type-dependent manner. CCN2 is critical for RPC-specific expression of structural collagen genes, retinal cell viability, and RGC specification from RPCs.

ABSTRACT BODY:

Purpose: To investigate choroidal neovascularization (CNV) types 1 and 2 in non-consecutive cases of central serous chorioretinopathy (CSCR) and its response to the best treatment.

Methods: We retrospectively evaluated 35 non-consecutive cases of CSCR for the presence of CNV types 1 and 2 during a 5-year follow-up. Those which developed CNV were submitted to monthly anti-VEGF applications for six months (either Ranibizumab, Bevacizumab or Aflibercept). Initially, the best corrected visual acuity ranged from 20/40 to 20/60 in the eyes presenting CSCR.

Results: During follow-up, we found three cases with evolving CNV: two were type 1 CNV and one was type 2. Among the eyes that developed CNV, no improve in visual acuity was observed, despite of the rigorous treatment and follow up.

Conclusions: Even though choroidal neovascularization type 1 is the most common reported CNV developed in such cases, CNV type 2 can occur in CSCR, and the outcome may be similar, with worsening in visual acuity prognosis regardless of best treatment.

ABSTRACT BODY:

Purpose: Overcoming retinal ganglionic cell (RGC) death induced by ischemia reperfusion injury and optic nerve transection is necessary for successful whole eye transplantation (WET). Current organ transplants use tissue preservatives like University of Wisconsin (UW) solution. We tested UW and a modified version including $BaCl_2$ and valproic acid (mUW) as RGC preservation solutions in an orthotopic rodent WET.

Methods: Untreated naïve eyes from 14-to-16-week-old male Brown Norway rats (n=32) were harvested and retinas were stained by immunohistochemistry (IHC) for Brn3a to quantify RGC preservation and phospho-c-Jun (PNJ) for apoptotic signaling. Donor eyes were then intravitreally injected with 10 µL of heparinized saline (n=3), UW (n=5), mUW (n=5), or not injected at all (n=3) and hemifacial flaps with donor eyes were harvested for WET. At POD2, transplanted and native (recipient, untreated) eyes were enucleated and retinas were prepared for IHC analysis. Continuous variables are presented as mean (±standard error) and compared using one-way ANOVA and two sample Z tests.

Results: Naïve retinas expressed 102.4±3.2k Brn3a+ RGCs with a 12% background expression of PNJ+ signal. At POD2, native recipient retinas show 107.8±4.0k Brn3a+ RGCs with 9% co-staining for PNJ+. In the untreated WET condition, retinas show 114.6k±5.6k Brn3a+ RGCs with 39% co-staining for PNJ+, a significant increase from the naïve condition ($P<0.05$). In the saline condition, retinas show 90.4±8.8k Brn3a+ RGCs with 21% co-staining for PNJ+, a significant increase from the naïve condition ($P<0.05$). UW treated retinas show 78.7±4.5k Brn3a+ RGCs with 1% co-staining for PNJ+. mUW treated retinas show 88.9±4.9k Brn3a+ RGCs with 2% co-staining for PNJ+. UW and mUW are not statistically different from one another ($P>0.05$) and both provided a significant reduction in RGC apoptosis in the setting of WET at POD2 ($P<0.05$).

Conclusions: We have established a novel system to assess RGC preservation and apoptosis post-WET. Injecting UW-based preservation solutions represents a promising strategy for RGC survival post WET. UW and mUW reduced apoptotic signaling compared to no treatment and saline in donor eyes at POD2 after WET. Future research will include monitoring Brn3a+ and PNJ+ expression at other timepoints and analyzing other apoptotic markers.

ABSTRACT BODY:

Purpose: To identify the most critical diagnostic features that differentiate ABCA4 disease from its numerous monogenic phenocopying retinal disorders.

Methods: Clinical and demographic features from a large cohort of 407 genetically-confirmed ABCA4 disease patients were compared to 68 patients harboring causal variants in various retinal dystrophy genes known to phenocopy ABCA4. Clinical data analyzed in both groups included detailed clinical and family histories, multimodal retinal imaging (fundus photographs, 488-nm, 521-nm and 787-nm AF, spectral domain-optical coherence tomography) and full-field electroretinogram (ffERG) testing.

Results: We identified 6 predominant phenotypes of ABCA4 disease that exhibit significant clinical overlap with approximately 43 different retinal dystrophy genes. In milder phenotypes such as bull's eye maculopathy (BEM), ABCA4 was most effectively distinguished from genes such as CRX, GUCY2D, RPGR and PROM1 by the age at clinical presentation ($p<0.001$). Age was also a critical factor between ABCA4 and RP1L1-associated occult macular dystrophy (OMD); however, non-retinal features such as the presence of nystagmus were considered for early onset OMD-associated genes like CNGA3 and CNGB3. In the most advanced clinical stages characterized by widespread degeneration across the posterior pole, differential diagnoses extended to non-maculopathy genes such as RPE65 and CERKL. Differentiating factors included identifying degenerative progression patterns and delayed peripapillary atrophy although symptomatic history was singularly most effective ($p<0.001$). Several genes such as PRPH2 and ROM1 phenocopied multiple pathognomonic features of ABCA4 disease and required more in-depth characterization such as fleck morphology and total area of the spared foveal region ($p<0.00001$). With some exceptions, ffERG, visual acuity and family history were the least effective considerations for diagnostic accuracy.

Conclusions: The clinical spectrum of ABCA4 is phenocopied, to varying degrees, by over 40 different retinal dystrophy genes. The list of differential diagnoses changes according to the various clinical stages of ABCA4. In the vast majority of cases, individual demographic considerations such as the age at presentation or symptomatic history are sufficient for making an accurate diagnosis.

ABSTRACT BODY:

Purpose: Retinal organoids (RO) generated from human induced pluripotent stem cells (hiPSC) constitute important in-vitro tools for retinal disease modeling and therapeutic drug development. However, low organoid yield and variability between batches of RO cultures hinder the use of these models in translational applications that require a high level of reproducibility for quantitative analyses. Likewise, lengthy culture times make the model impractical for drug screening purposes. Therefore, we set out to optimize current protocols to overcome these limitations.

Methods: Two different wild-type hiPSC lines were used for RO generation using the well-established protocol by Zhong et al. (2014). Five different media supplementation regimens of were tested on RO cultures starting at 63 days of differentiation: 1μM retinoic acid (RA), 10μM RA, 1μM 9-cis retinal (9cisRAL), 10μM 9cisRAL, and no supplementation. RO yield and photoreceptor outer segment (OS) length were longitudinally assessed in live organoids from each condition over a 4-month period. Additionally, ROs were collected at various time points, fixed, and their composition was evaluated by immunofluorescent staining and confocal microscopy with image quantification using FIJI software.

Results: Compared to other supplementation conditions, RO cultures that were supplemented with 9cisRAL displayed higher yield, increased OS length, and accelerated photoreceptor differentiation.

Conclusions: In this work we evaluated the performance of 5 different media supplementation regimens on the yield and quality of RO generation, to identify the most robust conditions for quantitative translational applications. We found that even though all tested conditions were able to produce RO with all the different retinal cell types and with photoreceptors displaying outer segment structures, 9cisRAL produced better RO yield than other conditions. Moreover, this condition accelerated OS development by approximately 30 days and produced longer OS.

ABSTRACT BODY:

Purpose: To investigate the progression of visual impairment at 12 months on various visual function tests in dry age-related macular degeneration (AMD).

Methods: Visual function of 44 participants recruited during the baseline study were re-assessed at 12 months. Participants with varying severity were classified into 1) Healthy aging (N=9), 2) intermediate AMD (iAMD) without subretinal drusenoid deposits (SDD) (N=17), 3) iAMD with SDD (N=10) and 4) non-foveal atrophy (N=8). Changes at 12 months in best corrected visual acuity (BCVA), low luminance visual acuity (LLVA), low luminance deficit (LLD), low luminance questionnaire (LLQ), mean scotopic perimetry, rod intercept time (RIT) and photopic ERGs were analysed using paired t-tests or Wilcoxon matched pairs signed rank test.

Results: Compared to baseline, delayed rod recovery in iAMD group without SDD group (p=0.043) was observed at 12 months. Lower composite scores on LLQ questionnaire were noted after 1-year review only in eyes with non-foveal atrophy (p=0.016). A decrease in BCVA of 4.5 ETDRS letters was observed in iAMD with SDD group (p= 0.035) and eyes with atrophic changes (p=0.008) at 12 months. There was no change over time in any other functional tests.

Conclusions: Rod recovery test is able to identify worsening of visual function in eyes with iAMD without SDD by 12 months while deterioration of LLQ score was observed in eyes with non-foveal atrophy only. These changes will inform future clinical trial designs in AMD.

ABSTRACT BODY:

Purpose: To measure the levels of VEGF in aqueous before and after treatment in patients with diabetic retinopathy treated with anti-VEGF agents. This was compared to VEGF levels in control eyes

Methods: The study was approved by the local University IRB. Aqueous samples were collected at the time of paracentesis following each intravitreal injection of an anti-VEGF agent given serially every 4 – 6 weeks in patients with proliferative diabetic retinopathy (PDR) or diabetic macular edema (DME). The control eyes consisted of aqueous collected from patients without diabetes or any retinal disease, undergoing cataract surgery. These samples were immediately stored in -80^{0} C freezer. At the time of analysis, aqueous samples were thawed at room temperature and VEGF (pg/ml) levels were measured using human premixed multi-analyte kit and magnetic bead assay on Luminex MAGPIX analyzer (Austin, TX, USA).

Results: In 203 samples from 59 eyes, the average VEGF level from the first sample measured in each eye was 198.3 pg/ml. This decreased significantly to an average level of 26.5 pg/ml in the last sample measured from each eye after 2-9 injections of an anti-VEGF agent (average, 3.4 injections). In 64 control eyes, the average level of VEGF was 34.06 pg/ml. The change in VEGF levels correlated with the retinal thickness on OCT

Conclusions: Aqueous levels of VEGF can be easily measured at every injection in patients with diabetic retinopathy. Aqueous levels of VEGF were significantly reduced after treatment with anti-VEGF agents. With the ease of obtaining the aqueous sample and measuring the VEGF levels, this maybe a useful parameter in the future, in addition to visual acuity and retinal thickness, to possibly personalize the treatment of patients with diabetic retinopathy.

TITLE: Prompt Primary Cyclophotocoagulation with Subsequent Aqueous Shunt as Needed for Neovascular Glaucoma with Synechial Angle Closure

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Wang, M. Qiu, Ophthalmology and Visual Science, The University of Chicago Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Jessie Wang: Commercial Relationship: Code N (No Commercial Relationship) | Mary Qiu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In acute NVG, implanting an aqueous shunt into eyes with active anterior segment neovascularization (NV) increases bleeding related complications. Prompt anti-VEGF rapidly regresses NV but is ineffective at lowering IOP when the angle is already synechially closed. CPC has historically been reserved for eyes with poor visual potential. The purpose of this case series is to describe a single surgeon's experience utilizing prompt CPC with prior or concurrent anti-VEGF and subsequent aqueous shunt as needed in NVG eyes with synechial angle closure, regardless of visual potential.

Methods: A retrospective chart review was performed for NVG patients with uncontrolled IOP, active anterior segment NV, a synechially closed angle, no contraindications to prompt anti-VEGF, CPC within 3 days of presentation, and at least 6 months of follow-up.

Results: Seven patients (3 male, 4 female, all African American) with mean age 63.9 years were included. Underlying etiologies were PDR (N=3), CRVO (N=3), and chronic RD (N=1). All patients received prompt intravitreal anti-VEGF on the day of acute presentation or within 3 days at the time of CPC. Patients received ongoing anti-VEGF injections and PRP at the discretion of the retina service. Five patients did not require subsequent aqueous shunts through a mean follow-up of 14.8 months; most recent visual acuities ranged from 20/50 to LP, and IOPs ranged from 4-20mmHg on 0-3 IOP-lowering medications. Two patients who required subsequent tubes (1 Ahmed 5 weeks later, 1 Baerveldt-350 11 weeks later) had resolution of active anterior segment NV by the time of surgery, and phaco could be performed to facilitate sulcus tube placement. At most recent follow-up (26 and 7 months), visual acuities were 20/40 and 20/150 with normal IOP. No eyes developed uncontrolled anterior segment inflammation, macular edema, or phthisis.

Conclusions: Prompt primary CPC within 3 days, with prior or concurrent anti-VEGF, is an effective strategy to immediately lower IOP in acute NVG eyes with active anterior segment NV and synechially closed angles, regardless of visual potential. If IOP becomes uncontrolled later, an aqueous shunt can be implanted in a controlled setting after active anterior segment NV has regressed. Further research is needed to compare outcomes of prompt CPC vs aqueous shunt in acute NVG eyes with completely synechially closed angles.

ABSTRACT BODY:

Purpose: The visual field (VF) exam, especially the 24-2 or 30-2 version, is commonly used when diagnosing glaucoma. The exam tests patient response to stimuli and summarizes findings in a report. This study evaluates the potential of a machine learning based approach for glaucoma detection using a VF report. This automated approach has the potential to help specialists make better-informed decisions, to optimize screening and to help triage referrals.

Methods: We collected 144 VF exam reports for this study. There were 28 women and 44 men (average 67 years old), and both eyes were examined. Exams were either 24-2 (58%) or 30-2 (42%). A specialist reviewed the patient charts and labelled the reports as glaucomatous (66%) or not (33%). We separated the reports into two datasets, “training” (70%) and “testing” (30%), each with the same distribution of glaucomatous eyes. For every report, we collected the dB values for each data point on the visual sensitivity map, total deviation, and standard deviation grids. The 24-2 exam has fewer grid points than 30-2, so the 24-2 datasets had null values for the corresponding plot points present in the 30-2 but not 24-2. We also recorded the fixation monitor and losses. We then cleaned the data to prepare it for analysis and applied an xgb machine learning model to the “training” dataset. We selected XGBoost because it can be trained on datasets with null values and still produce high-quality results. We then evaluated the model by running our model on the “testing” dataset and measured precision and area under the curve (AUC). We also used cross-validation to avoid overfitting.

Results: We achieved 92% precision (in 92% of cases it will detect a glaucomatous patient) and an AUC score of 82% (in 82% of cases it will accurately classify the patient as glaucomatous or not, indicating minimal false negatives). Out of 239 features, 203 were unnecessary for the prediction to achieve the above results.

Conclusions: We developed a reliable automated glaucoma detection approach that requires only 36 data points from a VF exam. This approach could be used to optimize referrals. Further, combining this model with portable VF exams could improve access to vision screening and hence early detection of glaucoma in rural areas. Further testing on large and diverse samples is needed to validate our findings and to discover additional insights.

ABSTRACT BODY:

Purpose: Prospective clinical trials in ophthalmology have historically struggled to enroll underrepresented racial and ethnic groups. In this study, we reviewed screening logs documenting consent or refusal to participate in prospective clinical studies. The purpose was to determine if specific patient and research personnel characteristics, such as demographics and languages spoken, influenced recruitment.

Methods: Retrospective cohort study at an urban academic hospital. Screening logs from 8 prospective clinical studies between 2015-2021 with a total of 1290 patients were included; demographics (age, gender, race/ethnicity, primary language, insurance status) were collected via electronic medical record, socioeconomic status (SES) was determined via area-deprivation index scores. Research staff demographics were collected via survey. Variables were analyzed using chi-square tests and odds ratios were calculated by multivariate logistic regressions.

Results: Black patients (OR=0.32, 95% CI 0.24-0.44; p<0.001) and Hispanic/Latino patients (OR=0.30, 95% CI 0.20-0.46; p<0.001) were significantly less likely to consent compared to White patients, even after adjusting for gender, language, SES, and insurance status. Males (OR=1.30, 95% CI 1.01-1.68; p=0.04) and those insured through Medicaid compared to Medicare (OR=1.6, 95% CI 1.30-2.16; p<0.001) were significantly more likely to consent, and patients with lower SES were significantly less likely to consent (OR=0.43, 95% CI 0.33-0.55; p<0.001). Concordance between patient and research staff gender decreased odds of enrollment (OR=0.71, 95% CI 0.54-0.93; p=0.014), while concordance in race and ethnicity (OR=2.98, 95% CI 2.14-4.16; p<0.001) significantly increased odds of enrollment. Patient’s primary language, concordance between patient and research staff language, and study design (interventional vs non-interventional) did not significantly influence the odds of participation.

Conclusions: Patients from racial and ethnic minority groups and low socioeconomic backgrounds were significantly less likely to participate in ophthalmic clinical studies. Notably, concordance of race/ethnicity and gender discordance between patients and research staff significantly increased patient enrollment, despite controlling for language. This study underscores the necessity of diversity in clinical research teams to decrease disparities amongst study subject populations.

ABSTRACT BODY:

Purpose: Single-cell RNA sequencing (scRNA-seq) has revolutionized our understanding of ocular gene expression. However, analysis of scRNA-seq data is time consuming and requires a degree of bioinformatic expertise. We developed the free online platform Spectacle to provide rapid, interactive access to scRNA-seq data. Spectacle contains over thirty fully processed datasets that collectively contain 1.5 million cells across the cornea, iris, limbus, trabecular meshwork, retina, retinal organoids, RPE, choroid, and sclera.

Methods: We reprocessed scRNA-seq data from thirty-one previously published ocular scRNA-seq manuscripts with our R package cellcuratoR, which transforms expression matrices into interactive objects within R Shiny. For over 90% of datasets, the exact clustering coordinates have been recaptured, which simplifies comparison with figures from existing manuscripts.

Results: Like other scRNA-seq visualization tools, Spectacle supports interactive exploration of cell clustering and gene expression through dot plots, heatmaps, and violin plots. However, a growing number of scRNA-seq studies compare gene expression across different biological conditions. Spectacle uniquely supports such studies and facilitates sophisticated, biologically driven analyses. For example, Spectacle powers flexible differential expression to identify genes enriched with different biological conditions (e.g., health versus disease) (Figure 1). In addition, cells can be reclustered to search for rare subpopulations of cells with certain biological characteristics. Finally, Spectacle can simultaneously compare gene expression across multiple different data sets, increasing confidence that a gene is expressed in a particular cell type or enriched with a particular biological feature (e.g., enriched in foveal retinal cells). Spectacle is freely accessible online at https://singlecell-eye.org.

Conclusions: Spectacle is a free, interactive resource that powers sophisticated, user-driven biological analyses with a very large collection of ocular scRNA-seq studies.

ABSTRACT BODY:

Purpose: Nonsense mutations in eukaryotic biology cause diverse diseases due to the creation of premature termination codon that results in truncated protein products. These diseases are often rare and ultra-rare, with an unmet medical need for therapeutic development. We have reported a KCNJ13 gene homozygous nonsense mutation c.158G>A, p.Trp53*.in a patient, and a c.496C>T, p.Arg166* nonsense mutation was reported earlier that caused Leber Congenital Amaurosis. Inwardly rectifying potassium channel (Kir7.1) is present in retinal pigment epithelial cells encoded by the KCNJ13 gene. This study aims to use engineered tRNA for the nonsense suppressing readthrough to rescue channel function.

Methods: HEK293 cells were co-transfected with a control plasmid (a Mo2RD reporter plasmid with either TAG or TGA codon) and a GFP tagged anticodon-engineered tRNA plasmid (4X Trp TAG 2-1 or 4X Arg TGA 3-1). The cells were imaged using a confocal microscope. The functionality of these plasmids to restore Kir7.1 current was assessed in a heterologous system expressing two GFP tagged nonfunctional nonsense mutation constructs, W53* or R166*. To study this, HEK293 cells were co-transfected with either R166*-eGFP-Kir7.1 plasmid along with 4x-Arg TGA, or W53*-eGFP-Kir7.1 plasmid along with 4x-Trp TAG. 72 hours post-transfection, cells were assayed for Kir7.1 current by whole-cell patch-clamp.

Results: All transfected cells showed red fluorescence indicating PTC correction for either TAG or TGA nonsense mutation with 80% transfection efficiency. Negative control experiments using a scrambled tRNA did not demonstrate any red fluorescence. HEK293 cells expressing W53* plasmid, when co-expressed 4X Trp TAG 2-1, we found expression Kir7.1 protein on the membrane compared to cytoplasmic expressions in the non treated cells. Biophysical properties of the Kir7.1 current like current-voltage plot, blocker sensitivity, and activation by Rb+ persisted in cells treated with 4X Trp TAG 2-1. Evaluation of the functional restoration of R166* mutation is underway.

Conclusions: Expression of red fluorescence after treating with respective tRNA treatment for Mo2 RD carrying nonsense mutation codons indicate normal protein translation by incorporating a wildtype amino acid. The restoration of Kir7.1 protein expression through membrane localization and functional restoration further assures the therapeutic use of engineered tRNA to correct nonsense mutation errors.

ABSTRACT BODY:

Purpose: To assess the relationship between optical coherence tomography angiography (OCTA) parameters at the baseline and treatment requirements over 1-year in eyes with diabetic macular edema (DME).

Methods: We followed one eye of each patient with DME without treatment in the preceding 12 months prospectively over one year. Participants underwent 3x3-mm OCTA scans centered on the fovea using Avanti (Optovue) at baseline. DME was defined as eyes with any fluid detected by a custom algorithm in a 3x3-mm area. We measured the foveal avascular zone (FAZ) and extrafoveal (excluding the central 1-mm circle) avascular area (EAA) in the superficial vascular complex (SVC), intermediate capillary plexus (ICP), and deep capillary plexus (DCP). Fluid volume (FV) was assessed in the inner nuclear layer (INL) and outer plexus layer (OPL). Patients received treatment for DME per standard of care. The primary outcome measure was the predictive value of baseline OCTA parameters for treatment requirements for one year.

Results: We included 66 eyes (mean 60 years old, 27 female). The mean number of treatments over 1 year was xx (range 0 to 14), and the mean number of visits was 1.4 ± 2.7 (range 0 to 14). Twenty-three eyes (35%) underwent treatment during the follow-up. These eyes were significantly younger ($P = 0.027$) and had greater FV in the INL and OPL ($P = 0.017$ and $P = 0.017$) at the baseline than eyes without treatment over 1 year. Univariate analyses showed significant associations with the number of treatments for age (rho = -0.28, $P = 0.025$), FV in the INL ($R = 0.35$, $P = 0.0083$), FV in the OPL ($R = 0.38$, $P = 0.0003$), and DR severity ($R = 0.30$, $P = 0.016$), but not for FAZ, EAA in all layers, and baseline central subfoveal thickness ($P > 0.05$). In a multivariate linear regression model ($R^2 = 0.36$), FV in the OPL (Standard $\beta = 0.35$, $P = 0.016$) and DR severity (Standard $\beta = 0.36$, $P = 0.0062$) were significant factors.

Conclusions: Greater FV at baseline is a predictor of greater treatment frequency in DME. The vascular metrics at baseline does not predict treatment requirement.

ABSTRACT BODY:

Purpose: To detect released histone in the vitreous space of patients with various retinal diseases, and to identify its role and activity using the retinal degeneration mice model.

Methods: Vitreous samples of patients were collected during vitrectomy and the histone concentration was tested by enzyme-linked immunosorbent assay. And a retinal degeneration mouse disease model was conducted by knocking out the nr2e3 gene. And the released extracellular histone in mice retina was verified by western blot and immunofluorescent staining. Besides, subretinal injection and intravitreal injection were utilized to deliver anti-Histone into the retina of nr2e3 knockout mice. Optical coherence tomography (OCT), fundus photography, fundus fluorescein angiography, and ERG were used to track the morphology changes over time.

Results: Released histones were detected in the vitreous space of patients with different retinal diseases. And in the retina of nr2e3 knockout mice, histone was also observed releasing from the nucleus of dying photoreceptor cells and then acting as damage-associated molecular pattern molecules when they were released into extracellular space. Interestingly, classic rosettes lesions of nr2e3 knockout mice usually appear by 12 days after birth, but the released histone and activated microglial appeared earlier than rosettes. Moreover, histone was also released by microglial cells via extracellular traps. After anti-Histone treatment by subretinal injection and intravitreal injection in postnatal 14 days mice, the number of the rosettes in the treated eyes was significantly less than that of the untreated control eyes at 1 month after injection tracked by fundus photography and OCT.

Conclusions: Our findings suggest that histones can be released from retinas with retinal diseases and the extracellular histone may act as the damage-associated molecular pattern molecules inducing the proinflammatory process thereby cause tissue toxicity.

TITLE: A potential role of cyclic dependent kinase 1 (CDK1) in late stage of retinal degeneration

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Zhou, Ophthalmology department, Lunds Universitet, Lund, SWEDEN|

Commercial Relationships Disclosure: Jiaming Zhou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) refers to a group of inherited disorders that lead to the dysfunction and death of photoreceptors, which causes progressive vision loss, and there is in principle no treatment available. The cGMP-PKG system has been suggested as a disease driver in several mouse RP models, although the downstream signaling of this enzyme system has not been clarified. Here we investigate the cGMP-PKG-system with the aim to reveal its potential target(s), that may have a direct detrimental effect during retinal degeneration.

Methods: With the aid of organotypic retinal explant cultures from a mouse-based disease model, i.e. the rd1 mouse, we added cGMP analogues to inhibit PKG in retinal explants from rd1. Mass spectrometry followed by peptide enrichment was then done to study the cGMP-PKG dependent signaling. Via a bioinformatics analysis, we identified downstream targets regulated by this system, and selected cyclin dependent kinase 1 (CDK1) for further validation. The expression of CDK1 within photoreceptors was compared between the rd1 model and its healthy, normal wild-type counterparts. CDK1 expression was also observed after various lengths of pharmacological inhibition of PKG during culturing of rd1 explants, to further assess the association between cGMP-PKG and CDK1. Co-staining with two cell death markers, namely acetylated lysine and TUNEL, was performed to study the possible involvement of CDK1 during photoreceptor degeneration.

Results: We observed that CDK1 was expressed in rd1 photoreceptors while no expression was noticed in the wt peers. With PKG manipulation of rd1 retinal explants, we could not find any alternation of CDK1 expression after 2 hours nor after 2 days of PKG inhibition, respectively, while CDK1 was lower expressed after 4 days treatment, compared to non-treated counterparts. Also, we found a high overlap of CDK1-positive and TUNEL-positive cells, as well as a partial overlap of CDK1-positive and acetylated lysine-negatively cells, according to the data from the co-staining of in vivo retinas.

Conclusions: Our results, particularly the overlap of CDK1 and TUNEL positive cells, suggest that CDK1 could be a downstream effector of the cGMP-PKG system and that it may be directly connected to the cell death process. Further studies of the CDK1 enzyme during retinal degeneration may therefore put it forward as a potential target for neuroprotection.

ABSTRACT BODY:

Purpose: Effective therapies to manage infectious keratitis are limited and rose bengal photodynamic antimicrobial therapy (RB-PDAT) is an emerging adjunct treatment (AJO 2019 PMID: 31493402). However, the antifungal activity of the photosensitizers on yeast species is unknown. We report the in vitro fungicidal effect of research (RB-1) versus clinical grade (RB-2) photosensitizers for RB-PDAT on Candida spp. Growth curve analysis was performed to assess the impact of non-irradiated rose bengal disodium (RBD) and lactone (RBL) on the metabolic activity of Candida spp. prior to photoactivation.

Methods: Candida albicans (CA, n=2) and Candida parapsilosis (CP, n=2) isolates were inoculated in tryptic soy broth (TSB) at 1.5×10^7 CFU/mL then 0.1% RB-1 or 0.1% RB-2 in 0.9% sodium chloride. Aliquots were plated on Sabourad-Dextrose agar in 3 groups: 1) Control (no photosensitizer/no irradiation); 2) Photosensitizer/No Irradiation; 3) Photosensitizer/Irradiation with 525 nm green LED light for 15 minutes at 5.4 J/cm2. After 72 hours of incubation at 37 degrees C, plates were photographed. Subsequently, three groups of 8 Candida spp. isolates (CA n=3, CP n=3, standard strains n=2, ATCC 90028, ATCC 22019) were prepared at 1.5×10^3 CFU/mL and inoculated in 1) TSB only 2) 0.01% RBD and 3) 0.01% RBL. 200µl samples were loaded onto a 96-well plate in triplicate and growth kinetics were measured on a Fluostar Omega instrument over 48 hours.

Results: Fungicidal activity (>95% elimination) was observed in all strains treated with RB-PDAT, whereas organisms that did not receive RB-PDAT grew confluent colonies with zero growth inhibition. Growth curve kinetics of Candida spp. prior to photoactivation showed no differences in ATCC CA, ATCC CP, CP-2 and CP-3 organisms in RBD. CA-2, CA-3, CA-4, and CP-1 in RBD versus RBL, showed increased growth in RBL at the stationary phase.

Conclusions: Candida spp. isolates recovered from patients treated with disodium RB were susceptible to in vitro RB-PDAT irradiation. A comparison of Candida spp. growth curves in non-irradiated RBD versus RBL showed no difference in optical density with either photosensitizer, suggesting that the solutions alone are insufficient to inhibit fungal proliferation.

TITLE: Can EHR Data Automatically Calculate Ophthalmic Quality Measures? The Impact of Baselines

SESSION TITLE: Using Technology for Care Delivery and Improvement

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Hribar, DMICE, Oregon Health & Science University School of Medicine, Portland, Oregon, UNITED STATES|M. Hribar, J.S. Chen, A. Chen, Ophthalmology, Oregon Health & Science University School of Medicine, Portland, Oregon, UNITED STATES|M.F. Chiang, National Eye Institute, Bethesda, Maryland, UNITED STATES|

ABSTRACT BODY:

Purpose: The American Academy of Ophthalmology (AAO) ophthalmic clinical quality measures (QM) define successful clinical outcomes for ophthalmic care. Of the AAO's 30 ophthalmic QMs in 2020, 17 of them use an improvement over baseline as the outcome. Nevertheless, the QM definitions do not provide details about what baseline value to use, which makes automatic calculation of the quality measure difficult and variable.

Methods: We evaluated two QMs using different baselines in two different patient populations: 1) Oregon Health & Science University (OHSU) clinical practices and 2) the IRIS Registry. We analyzed IRIS 39, Glaucoma – Intraocular Pressure Reduction Following Trabeculectomy or an Aqueous Shunt Procedure, and IRIS 59, Regaining Vision after Cataract Surgery using surgeries that occurred between January 1, 2019 and December 31, 2019. Neither measure defined the time frame or rules for selecting which values to use as baseline. We chose to calculate IRIS 39 using the best (lowest) and worst (highest) interocular pressure (IOP) values measured within 1 year prior to surgery as baselines, and chose the best (lowest) and worst (highest) visual acuity (VA) values measured within 30 days prior to surgery for baselines in IRIS 59.The results for the different baselines were compared using Z tests.

Results: The percentage of patients who met each of the measures varied at both OHSU and in the IRIS Registry depending on baseline used (Figures 1 and 2). For both measures and populations, the worst baseline values resulted in higher percentage of patients meeting the measure; in all cases over 70% of patients met the measure (the benchmark for full reimbursement), but the best baseline values achieved this benchmark in only one case (IRIS 39 in IRIS Registry). The difference in the % of patients meeting the measure for different baselines were statistically significant ($p < 0.01$) for both measures in both populations.

Conclusions: This study shows that baseline values have an impact on the number of patients who meet QMs. Careful definition of baselines has important implications for healthcare quality and reimbursement; without these definitions, electronic health records cannot accurately and consistently calculate QMs. Moreover, explicit baseline definitions are crucial for demonstrating effectiveness of treatments in research and clinical trials.

ABSTRACT BODY:

Purpose: Mutations in optineurin (OPTN) are associated with familial normal tension glaucoma and other neurodegenerative diseases, yet their contribution to visual impairments remain unclear. Recently, in vivo longitudinal assessments on transgenic mouse models revealed that E50K OPTN was associated with differential age-dependent vision loss, whereas knocking out OPTN appeared to preserve visual function [IOVS 2021; 62(8):2385]. Here, we aimed to determine the role of E50K OPTN on underlying structural integrity in the mouse visual pathway using diffusion tensor imaging (DTI).

Methods: Twenty-eight 24-month-old mice with C57BL/6 background were used: wildtype (WT; n=9), homozygous OPTN knock-out (mOPTN-KO; n=8), hemizygous mouse E50K OPTN knock-in (mE50K het; n=3), homozygous mouse E50K OPTN knock-in (mE50K homoz; n=5), and human E50K OPTN bacterial artificial chromosome overexpression (hE50K BAC; n=3) (PMID: 31076632, 25818176). Ex vivo whole-brain DTI was acquired in 60 directions in a 7-Tesla MRI scanner. DTI parametric maps including fractional anisotropy (FA), axial diffusivity (AD), radial diffusivity (RD), and mean diffusivity (MD) maps were derived, and bilateral regions-of-interests (ROIs) were manually delineated for the optic nerve (ON) and anterior commissure (AC) on each map (Fig. 1). Results were analyzed using ANOVA and post-hoc tests.

Results: Significant group differences were observed in FA, RD, and MD but not AD for ON (ANOVA, $p<0.05$). No significant group difference was observed in either DTI map for AC ($p>0.05$). As shown in Fig. 2, Bonferroni-corrected post-hoc tests for ON revealed significantly lower FA in mE50K het and mE50K homoz relative to WT, along with significantly higher RD and MD in the same mE50K groups. Post-hoc analyses also revealed higher RD in mE50K het relative to hE50K BAC for ON.

Conclusions: The significant DTI differences in ON but not AC between WT and mE50K groups suggest the preferential disruption of structural integrity in the visual pathway upon a toxic gain of function mechanism from E50K OPTN. Such overall integrity loss as indicated by reduced FA appeared to be driven by increases in RD and MD, which are sensitive to glial activity and neuroinflammation. The non-significant differences between mOPTN-KO and WT suggest that suppression of OPTN might help preserve white matter structures from glaucomatous neurodegeneration.

TITLE: Assessing the short term visual and anatomical outcomes in ocular syphilis treated with adjunctive topical or oral steroids

SESSION TITLE: Anti inflammatory agents, antibiotics and antivirals

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Ishihara, S. Buscho, P. Gupta, Department of Ophthalmology and Visual Sciences, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Rhys Ishihara: Commercial Relationship: Code N (No Commercial Relationship) | Seth Buscho: Commercial Relationship: Code N (No Commercial Relationship) | Praveena Gupta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is very little documented about the use of adjunctive steroids for uveitis associated with ocular syphilis. Because little evidence exists for the route of steroid treatment, we compared the effectiveness between the use of adjunctive topical steroids versus oral steroids. We performed a retrospective, clinical study to learn about the anatomic and visual outcomes in ocular syphilis patients treated with adjunctive topical steroids or oral steroids.

Methods: Nine male patients aged 26 to 72 years old were identified with a diagnosis of ocular syphilis by a positive RPR, positive treponemal IgG/IgM, with associated bilateral anterior or posterior chamber inflammation. All patients were treated with IV penicillin and topical prednisolone acetate or high dose oral prednisone. Six patients were found to be treated with topical prednisolone acetate 1-2 days after starting treatment with penicillin. Three patients were treated with high dose oral prednisone 1-2 days after starting treatment with penicillin. Visual acuity and slit lamp findings (cells and flare) were documented at presentation. Outcomes were visual acuity and slit lamp findings at discharge from the hospital or first clinic follow up after discharge.

Results: Patients in the topical steroids group had an average presenting visual acuity of 20/400. There was improvement to 20/100 at a mean follow up of 16.1 days. Patients in the oral steroids group had an initial visual acuity of 20/100. There was visual improvement to 20/25 at a mean follow up of 8.3 days. Qualitatively, there was significant improvement of ocular inflammation in both groups, but there was swifter improvement in the oral steroids group.

Conclusions: There was a noticeable increase in the rate of improvement of visual and anatomical recovery in ocular syphilis patients treated with oral steroids in the short term. Also, average recovered visual acuity in the oral steroids group was significantly better than the topical group, although, the starting average visual acuity was worse in the topical group. However, this is a small study, and we are looking to expand our sample size to other sites. Furthermore, many of the patients were lost to follow up and more studies need to be performed to assess long term outcome.

ABSTRACT BODY:

Purpose: Bone marrow-derived activated monocytes and progenitor cells migrate to the retina in response to inflammation and neovascularization. Hypoxia-inducible factor-1α (HIF-1α) has been shown to contribute to the pathogenesis of neovascularization. However, contribution of monocyte-derived macrophages to neovascularization is largely unknown. We describe here the synthesis of a new hybrid nanoparticle for targeted delivery and gene silencing in activated monocytes that are associated with pathological neovascularization.

Methods: Single-cell RNAseq data analysis were performed to characterize HIF-1α mRNA expression in activated monocytes in mouse oxygen-induced retinopathy (OIR). HIF-1α targeted AS-shRNA-lipids were synthesized by conjugating diacyl-lipids to anti-sense short hairpin RNA with an anti-sense sequence complimentary to HIF-1α mRNA. The short hairpin RNA compounds were stabilized using 2'-O-methyl-protected ribonucleotides allowing in vivo delivery of AS-shRNA-lipid to the activated monocytes that are associated with neovascularization.

Results: HIF-1α mRNA expression was associated with MRC-1 positive activated monocytes. In addition, HIF-1α mRNA was induced in monocytes by exposing the cells to hypoxia, and the expression was inhibited by AS-HIF-1α-shRNA-lipid. CD14 mRNA expression was significantly elevated in monocytes that were exposed to hypoxia, suggesting monocyte activation. AS-HIF-1α-shRNA-lipid could significantly inhibit this activation. In addition, significant reduction of neovascularization was achieved in mouse OIR after intraperitoneal injection of AS-shRNA-lipids.

Conclusions: Inflammation and hypoxia could activate monocyte functions and inhibition of HIF-1α mRNA could recover these cells from activation. In summary, we have developed a novel method for targeted delivery and inhibit HIF-1α mRNA in activated monocytes in living ocular tissues using diacyl-lipid-conjugates of antisense short hairpin RNA (AS-shRNA-lipid) designed to target HIF-1α mRNA. These conjugates are readily internalized by activated monocytes that are associated with neovascularization in the living retina. These findings may provide a framework for a novel strategy to inhibit retinal neovascularization.

Keywords: targeted delivery, activated monocytes, gene therapy, short-hairpin RNA, neovascularization.

TITLE: Does Optic Flow Enhance Depth Perception in the Presence of Artificial Acuity Reduction?

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Liu, G.E. Legge, Psychology, University of Minnesota Twin Cities, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Siyun Liu: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Legge: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optic flow induced by self-motion can enhance depth perception in 3D space. For observers with reduced acuity and contrast sensitivity, motion cues might be helpful when pictorial and binocular depth cues are unreliable. Motion-related depth cues can be categorized as optical expansion when the observer approaches the fixated object, and motion parallax when the observer's motion is orthogonal. Is there a difference in the accuracy of depth perception with these two types of observer motion under conditions of blur? If yes, is the benefit due to the difference in starting and ending viewpoints, or does it require continuous motion?

Methods: We created a virtual 3D room containing a target cube on the floor and a reference sign. Two-second-long videos were rendered in five types: a single static view, optical expansion from continuous forward motion or the corresponding first and last static views, and motion parallax from continuous orthogonal motion or the corresponding first and last static views. Videos were prepared with three levels of calibrated blur—Moderate, Severe, and Profound with corresponding logMAR values of 0.95, 1.15, and 1.55. Ten normally sighted observers viewed the videos on a computer monitor. They judged how far the target cube was in front or behind the reference sign in feet by moving an on-screen slider.

Results: Averaged across the three blur levels, motion parallax reduced depth estimation errors by 47% and optical expansion by 10% compared to a single static view. The difference in performance between continuous motion and conditions with start-ending views was only significant in the Moderate blur condition ($p<.001$). In the Severe and Profound blur conditions, the difference between continuous motion and start-and-end static views was not significant.

Conclusions: Motion parallax yielded greater benefits in judging object depth than did optical expansion. Except in the Moderate blur condition, continuous motion was no more effective than static views at the beginning and end of the motion sequence. Together, these results indicate that motion cues are beneficial in judging object depth for conditions of artificial acuity reduction.

ABSTRACT BODY:

Purpose: To examine the post-operative outcomes of corticosteroid use prior to glaucoma surgery in the treatment of primary open angle glaucoma (POAG).

Methods: A retrospective cohort study was conducted using the TriNetX (Cambridge, MA, USA) electronic health records research network to identify patients who underwent glaucoma surgery for POAG, identified by ICD-10 and CPT code. Cases were stratified into two cohorts based on history of corticosteroid therapy of any kind for up to one year preceding surgery. Cohorts were matched for age, gender, and medical comorbidities (essential hypertension, diabetes mellitus, chronic lower respiratory disease, heart failure, nicotine dependence, alcohol related disorders, and body mass index). The primary outcomes were as follows: development of secondary glaucoma, ocular hypotony, hyphema, vitreous hemorrhage, choroidal hemorrhage, retinal detachment (RD) or tear (RT), iridocyclitis, macular edema (ME), cystoid macular degeneration (CMD), cataract, strabismus, secondary corneal edema, dry eye syndrome (DES), central retinal artery occlusion (CRAO), central retinal vein occlusion (CRVO), vitreous hemorrhage (VH), and revision of the aqueous shunt. Outcomes were compared between the cohorts after propensity score matching using logistic regression and greedy nearest-neighbor matching algorithm. The risk ratio (RR) was obtained, with a p-value <0.05 being considered as significant.

Results: A total of 6,494 eyes were included in the analysis with 3,247 cases in each of the cohorts. Cases with a history of steroid use had increased risk ($p<0.05$) for hypotony (RR 1.73, 95% CI 1.31-2.30), ME (RR 2.11, 95% 1.54-2.88), CMD (RR 1.88, 95% CI 1.43-2.47), choroidal hemorrhage (RR 1.79, 95% CI 1.0-3.18), cataract (RR 1.31, 95% CI 1.10-1.56), strabismus (RR 1.55, 95% CI 1.03-2.32), DES (RR 1.41, 95% CI 1.11-1.79), and need for aqueous shunt revision (RR 1.34, 95% CI 1.08-1.65). Lack of steroid use increased risk ($p<0.05$) for developing secondary glaucoma (RR 0.64, 95% CI 0.51-0.82). No significant difference was found in all other primary outcome measures.

Conclusions: History of any corticosteroid use is an important consideration for post-operative complications following glaucoma surgery. Limitations of this study included lack of data indicating route of corticosteroid administration and stratification based on type of glaucoma surgery (i.e., trabeculectomy versus aqueous drainage device).

ABSTRACT BODY:

Purpose: Many blinding diseases and aging impact specific geographic regions of the human retina, including the macula, the area responsible for our high-acuity color vision. Significant gaps in our knowledge about human vision exist due to technical barriers for studying phototransduction and light signal transmission specifically in the human macula. We aimed to establish criteria and methods for generating functionally viable peripheral and central human retina patches obtained from donor human eyes using ex vivo Electroretinography (ERG).

Methods: Eye bank autopsy eyes were recovered within 2-5 hours of death; organ donor eyes within 45 min - 2 hours following cardiac death (DCD), or 1 – 20 mins following circulatory arrest in brain dead donors (DBD), and within 5 mins of death from macaques. Eyes were transported to the laboratory in oxygenated Ames medium. Retinal punches were taken from the macula and periphery and perfused with Ames media at 35-37^{O}C in a custom ex vivo ERG device to measure light-induced electrical responses.

Results: We recorded ex vivo ERG a-waves from macular samples in autopsy eyes and in DCD eyes up to 5 hours postmortem. Photoresponse amplitudes in the DCD maculae were not different from those recorded from freshly dissected macaque maculae ($p=0.61$, n=3/5 human and macaque biological/technical replicates) but declined with increasing enucleation delay (decay time constant = 74 mins). ERG b-waves were not normally present in these donors (n=20), with one exception, where we could record ERG b-waves in the peripheral samples from a research donor who died of stroke (>2 hours enucleation delay). Using DBD eyes, we were able to consistently revive ERG b-waves when enucleation delay was under 20 mins (n=5/10 biological/technical replicates). DL-AP4, known to block mGluR signaling from photoreceptors to ON bipolar cells, abolished the b-wave both in peripheral and macular samples.

Conclusions: We established a method and distinct criteria for revival of ERG a- and b-waves in the human retina. We recorded the first ex vivo light responses from the human macula and used pharmacology to demonstrate that ERG b-wave in the human periphery and macula is mediated by photoreceptor-ON bipolar cell transmission. This approach enables future studies to advance our understanding of human vision, vision disorders and visual rehabilitation.

Commercial Relationships Disclosure: Gengxi Lu: Commercial Relationship: Code N (No Commercial Relationship) | Xuejun Qian: Commercial Relationship: Code N (No Commercial Relationship) | Runze Li: Commercial Relationship: Code N (No Commercial Relationship) | Yushun Zeng: Commercial Relationship: Code N (No Commercial Relationship) | Biju Thomas: Commercial Relationship: Code N (No Commercial Relationship) | Mark Humayun: Commercial Relationship: Code N (No Commercial Relationship) | Qifa Zhou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Current treatment strategy for blindness caused by retina degeneration is to use invasive retinal prostheses based on electric stimulation. We hypothesize that ultrasound stimulation can be a promising non-invasive retinal prosthesis by observing the ultrasound-evoked neuron activities in cortical visual circuits of retina degenerated rats. The relationships between the ultrasound center frequency and the stimulation efficiency is also investigated.

Methods: In vivo experiments were conducted on both normal rats and RCS retina degenerated rats. Self-designed transducers with different center frequencies were mounted on a 5-axis precision stage and were placed in front of the rat eye. For electrophysiological recording, a small craniotomy was made based on stereotactic coordinates to expose the superior colliculus or primary visual cortex, then the multi-electrode array was advanced. Experiments were conducted on 10 normal rats and 16 blind rats.

Results: We show that direct ultrasound retina stimulation can evoke neuron activities from the visual centers in normal and retinal degenerated blind rats (Fig. 1). The neuron activities induced by the focused 3.1-MHz transducer have shown a spatial resolution of 250±50 μm. Ultrasound frequencies ranging from 2 MHz to 8 MHz were tested. Higher frequencies are more efficient for neuron stimulation. Mechanical index (MI) to evoke neuron activities is lower at higher frequencies.

Conclusions: Our findings demonstrate that ultrasound stimulation of the retina in vivo can evoke neuron activities. Higher ultrasound frequency leads to a lower stimulation threshold. Ultrasound stimulation is a promising technology as a novel and non-invasive visual prosthesis for translational applications in blind patients.

TITLE: Proptosis secondary to poor ocular tethering from congenital aplasia / hypoplasia of multiple extraocular muscles

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Nadimpalli, J. Yu, L. Prasov, P. Williams, A. Jacobson, Ophthalmology, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Sameera Nadimpalli: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Yu: Commercial Relationship: Code N (No Commercial Relationship) | Lev Prasov: Commercial Relationship: Code N (No Commercial Relationship) | Pamela Williams: Commercial Relationship: Code N (No Commercial Relationship) | Adam Jacobson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe a case of an infant with unilateral proptosis and bilateral asymmetric extraocular muscle (EOM) aplasia / hypoplasia in the setting of bilateral posterior embryotoxon.

Methods: Observational case report

Results: A full-term newborn was consulted for evaluation of a wide nasal bridge and anisocoria. Birth history was significant for anti-phospholipid antibody syndrome in the mother. Family history revealed hypertelorism in the brother with limited negative work-up, bilateral congenital cataracts in the mother, and congenital cardiac abnormalities in the brother and mother. Newborn screen was normal and the newborn evaluation was notable for a large atrial septal defect. Ophthalmology exam showed blink to light vision OU, anisocoria symmetric in light and dark without an APD, abduction deficits OS > OD, adduction deficit OS, corneal haze OU, posterior embryotoxon OU, and normal remainder of exam. She was noted to have left eye buphthalmos versus proptosis and underwent exam under anesthesia (EUA) with MRI head / neck at 5 months. EUA revealed IOP 21 OD and 24 OS, corneal haze OU, megalocornea OU, gonioscopy with peripheral anterior synechiae to posterior embryotoxon OU, pachymetry 670s OU, and axial lengths of 20.24 OD and 20.73 OS. Fundus exam OU showed normal nerves with 0.1 cup to disc ratio, blunted foveal light reflex and was otherwise normal. MRI revealed right lateral rectus and left medial rectus hypoplasia and left lateral rectus aplasia and was otherwise unremarkable. Given the constellation of findings, genetic testing was recommended but deferred by parents other than testing for mucopolysaccaridoses, which was negative.

Conclusions: In this patient, left eye proptosis was mistaken for congenital glaucoma-related buphthalmos from an anterior segment dysgenesis syndrome. Proptosis in this case is likely related to poor ocular tethering from EOM hypoplasia / aplasia. The latter could be related to a primary neurocristopathy resulting in anterior segment dysgenesis and associated EOM abnormalities as previous studies have suggested that neural crest migration is required for EOM development. Alternatively and less likely, this may be a case of a congenital cranial disinnervation disorder with incidental posterior embryotoxon. While genetic testing would be useful, the parents have elected to defer further work-up at this time.

ABSTRACT BODY:

Purpose: Poly(methyl methacrylate) (PMMA) three-piece intraocular lenses (IOLs) have poor durability for manipulation, resulting in haptic fracture or permanent bending. This study evaluates the mechanical properties of PMMA IOL haptics through stress-strain analysis and bend testing before and after applying heat to the material to enhance the durability and flexibility.

Methods: PMMA haptic material is heat treated by a water bath, for clinical relevance, at 8 different temperatures, and mechanically tested in tension, compression, and bending procedures. This method is then applied to 20, three-piece intraocular lenses, of the same manufacture.

Results: Preliminary data from this study indicates that after heat was applied to the PMMA haptics, the Young's Modulus was decreased by approximately 10%, and the average load force was decreased by approximately 25%. Experimental results show that at bending angles of 75 degrees and more acute, there is progressive deformation of the PMMA haptics at room temperature. Heating the haptics from 40°C to 45°C, for five minutes, showed minimal deformation immediately after bending that resolved after 20 minutes. Heating the haptics at any temperature above 35°C for 10 minutes led to increased deformation, when compared to five minutes, that did not resolve after 20 minutes. When heated from 50°C to 55°C, the haptic deformation improved, but did not completely resolve after 20 minutes. When heated past 60°C for five minutes, the haptic material undergoes permanent plastic deformation before performing the bending procedures. The data collected from experimental bending procedures showed a trend that the PMMA haptic material did not permanently deform when heated for five minutes between 40-45° C. When heated past 50°C for five minutes, the haptic material undergoes permanent plastic deformation with loss of elastic memory after bending procedures.

Conclusions: Pre-heating of PMMA IOLs within particular temperature ranges decreases their stiffness, enhances their flexibility, and reduces capacity for permanent plastic deformation. Such treatments may allow increased use of conventional PMMA IOLs for surgeries where haptic manipulation is expected (i.e. scleral fixation) by reducing the risk of plastic deformation due to haptic bending.

ABSTRACT BODY:

Purpose: People with central field loss rely on peripheral vision to read. We introduce a letter-based perimetry method to assess letter recognition over the central region of the visual field (13.5° x 14.9°). Performance is compared with microperimetry (Macular Integrity Assessment; MAIA). We expect that letter-based perimetry can accurately map the scotoma. Reading is influenced by other processes not needed in light detection (e.g., crowding, letter recognition) and letter-based perimetry may be useful in predicting peripheral reading ability.

Methods: We report data from one participant with macular degeneration that completed letter-based perimetry and microperimetry monocularly with their better functioning eye (left). Fixation stability was 'stable' (95% BCEA = $1.8°^2$) with a preferred retinal locus below and to the left of the scotoma (approx. 8° in diameter). For letter perimetry, strings of three randomly chosen letters were presented briefly (200 ms) at controlled locations (n = 117) on a computer. Fixation was confirmed to be at the center of the screen using an eye tracker (Tobii Spectrum Pro; 300 Hz). The participant verbally reported any detected letters. Correct and incorrect responses were summed for each letter location and accuracy was computed. The participant chose a comfortable letter size for reading. For microperimetry, a 10-2 Cartesian grid was used with a 4-2 threshold strategy to obtain light sensitivity thresholds; 60 of these locations overlapped with the tested letter locations. Mean letter recognition accuracy was computed for each of the 60 locations by averaging the recognition accuracies of overlapping letters.

Results: To test how well letter-based perimetry was able to map the scotoma, the letter recognition accuracy for MAIA grid locations with low light sensitivity (<= 13 dB; n = 22 locations; mean = 3.05 dB) were compared to those areas with high light sensitivity (>= 17 dB; n = 38 locations; mean = 21.79 dB). Locations with low light sensitivity had significantly lower letter recognition accuracy (9.1%) than locations with high light sensitivity (41.0%; $T(58) = -6.62$; $p < 0.01$).

Conclusions: We introduce a letter-based perimetry task where letter recognition is assessed across the central visual field. Letter recognition for areas with low light sensitivity as measured with microperimetry was significantly lower than areas with high light sensitivity demonstrating that letter-based perimetry is useful to detect scotomas.

ABSTRACT BODY:

Purpose: Few genes are known to cause early-onset glaucoma, a severe disease affecting children and young adults. The overall purpose of this work is to identify novel early-onset glaucoma genes.

Methods: Whole-exome sequencing (WES) was conducted to identify variants in glaucoma families. A CRISPR-mediated mouse germline knock-in strategy was used to create a mutation equivalent to THBS1 R1034C. Mutant mice were evaluated for intraocular pressure (IOP), outflow facility, anterior segment histology and RGCs counts. The force field program-FoldX was used to determine the protein folding energy changes related to different mutations. The effect of mutations on extracellular matrix (ECM) was studied by site directed mutagenesis and in vitro expression.

Results: We identified novel heterozygous THBS1 missense alleles altering p.Arg1034, a highly conserved amino acid, in 3 unrelated and ethnically diverse families affected by congenital glaucoma with variable expressivity (two families with R1034C and one with R1034S). Both heterozygous and homozygous $Thbs1^{R1034C}$ mice exhibited elevated IOP (ANOVA, $P<0.001$), decreased aqueous outflow facility (43.3% and 40.5%, respectively), and RGCs loss (15.9% reduction in central retina and 22.2% in the peripheral), compared to wild type controls. Histology and electron microscopy revealed an aberrant accumulation of THBS1 in the TM ECM. FoldX suggested that the missense alleles destabilize the THBS1 structure causing protein aggregation by misfolding. Analysis using a mutagenesis series at Arg1034, including R1034C and R1034S, showed that the extent of THBS1 aggregation in ECM is correlated with the extent of mutation-related free unfolding energy. Structural ECM components, especially fibronectin, were also recruited to THBS1 depositions.

Conclusions: Our study suggests that missense variants altering THBS1 p.Arg1034 can elevate IOP through a mechanism involving aberrant TM extracellular THBS1 aggregation with compromised outflow. The role of THBS1 in the regulation of aqueous humor dynamics provides new opportunities for genetic testing and therapeutic intervention.

ABSTRACT BODY:

Purpose: Mitochondrial dysfunction of retinal pigment epithelial (RPE) cells plays a key role in age-related macular degeneration (AMD) pathogenesis. We have previously shown that RPE cells derived from AMD donors have a distinct mitochondrial gene expression profile as well as distinct phenotype when compared to age-matched controls. Here, we analyze the mitochondrial gene expression and function of these lines cultured on nitrite-modified extracellular matrix (ECM), an in vitro aged Bruch's membrane model, to investigate whether a nitrite-modified ECM alters mitochondrial function and gene expression in AMD-derived RPE.

Methods: iPSCs were generated from fibroblasts isolated from four AMD patients (2 atrophic and 2 exudative). RPE derived from iPSCs were generated using established protocols and analyzed by morphology, cell type specific marker expression, transepithelial resistance (TER), and phagocytosis of rod photoreceptor outer segments. Cells were cultured on nitrite ECM for two weeks and subject to cell viability and mitochondrial function analysis using the Seahorse platform. DNA microarray with 23,000 well annotated genes, including mitochondrial structure and function-related genes.

Results: iPSCs and differentiated RPE displayed cell-type-specific morphology, markers, TER, and phagocytic capacity. Cell viability and mitochondrial respiration were reduced in AMD-derived RPE cells on nitrite ECM, compared to cells cultured on unmodified ECM; mitochondrial related genes such as ATPase Cu++ transporting beta polypeptide (ATP7B), cytochrome P450 family 24 subfamily A polypeptide 1 (CYP24A1) and glutaminase 2 (GLS2) display a distinct expression pattern in AMD-derived RPE when cultured on nitrite-modified ECM compared to AMD-derived lines cultured on unmodified ECM.

Conclusions: Here, we provide evidence that nitrite modification of the ECM affect cell viability and mitochondrial function in iPSC-derived from AMD patients. Further exploration of the mitochondrial genes affected in this model may pave the way for novel treatments for AMD.

ABSTRACT BODY:

Purpose: Uveitis specialists represent a small group of subspecialists among academic ophthalmologists. To our knowledge, this is the first study to investigate sex differences in scholarly productivity, academic rank, and NIH funding among uveitis specialists.

Methods: This study was a cross-sectional study of academic uveitis specialists of 113 US ophthalmology programs. Using institutional websites, data on sex, residency graduation year, and academic rank were collected. The Scopus database was used to obtain each faculty's h-index, which is a measurement of publication productivity and citation impact, and m-quotient, which adjusts for a faculty's career duration. The NIH Research Portfolio Online Reporting Tool database was queried for data on NIH funding. Chi-square testing was used to analyze categorical values and Wilcoxon Rank Sum testing was used for continuous variables.

Results: A total of 106 academic uveitis specialists were identified, of whom 44 (41.5%) were female and 62 (58.5%) were male. A greater proportion of females vs. males were assistant professors [30 (68.2%) vs. 22 (35.5%); p=0.011] and a smaller proportion of females were full professors [4 (9.1%) vs. 24 (38.7%); p=0.008]. No significance difference was found among associate professors [female: 10 (22.7%) vs. male: 16 (25.8%); p=1.000]. Females had significantly lower median h-indices compared to their male counterparts (5.5 vs. 14.0; p=0.036), but similar median m-quotients (0.5 vs 0.5; p=1.000). Females had a shorter median career duration based on their residency graduation year compared to males (8.0 vs 19.0 years; p <0.001). Among the 22 uveitis specialists who received NIH funding for research, of whom 7 (41.5%) were female and 15 (58.5%) were male, females had a median grant funding of $1.2M compared to $2.5M for males (p=1.000).

Conclusions: Female academic uveitis specialists are overrepresented among assistant professors and underrepresented among full professors. Although females had lower h-indices than male, there was no difference in m-quotients between sexes, which controlled for the specialists' career durations. These differences in scholarly productivity are therefore due to the difference in career duration between female and male specialists and indicates that women are equally as academically productive as their male counterparts.

ABSTRACT BODY:

Purpose: In recent years, innovations in tele-ophthalmology have shown promise in providing quality ophthalmic care to patients in low-access settings and high-risk environments such as the COVID-19 pandemic. Emergency departments and urgent centers may benefit from tele-ophthalmology applications; the tele-images can be sent to the covering ophthalmologist or, to another ED for evaluation of images prior to transferring the patient. In this study, we aimed to assess the ability of resident physicians to identify features of posterior-pole retinal pathology using tele-ophthalmology.

Methods: Retrospective study on 16 patients (32 eyes; 30 with retinal pathology and 2 controls) who presented to a retina clinic at an academic medical center. Automated OCT-B images with 3D topographic maps and fundus photographs of the posterior pole using a Topcon Maestro 3D OCT-1 unit were taken. Images were transmitted remotely to a resident physician who attempted to identify retina pathology using fundus photography and OCT. The same images were consequently evaluated by a retina specialist for grading. We then tested the concordance between diagnoses rendered via tele-OCT by the resident physician and the gold standard clinical examination (performed by the retina specialist) using Cohen's Kappa statistic (κ).

Results: An overall average of 79.9% concordance for 69 potential findings was obtained between the retina attending's diagnosis with clinical examination and the resident physician's diagnosis using tele-OCT/fundus images based on Cohen's Kappa statistic (κ). The concordance was lower in eyes with vitreous hemorrhage most likely due to the inferior quality fundus and OCT-B images. The resident exam also identified the presence of any macular pathology in all 30 eyes with macular pathology and correctly identified the controls, indicating 100% sensitivity for identifying abnormal findings using tele OCT/fundus images.

Conclusions: This study verifies the utility of resident screening of tele-OCT fundus and OCT-B images to identify retinal pathology. Tele-ophthalmology likely has a useful role in triaging retinal pathology whose outcomes could be affected by timely intervention. Many unnecessary emergency transfers may be avoided if the on-call ophthalmology residents are able to review the fundus and OCT images before hand.

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) is caused by gene-gene interactions. In 10 % of cases, POAG also segregates as an autosomal dominant (AD) trait that can show wide phenotypic variability. We hypothesize that this variability is caused by modifier genes that interact with AD disease genes. To detect significant gene-gene interactions, we designed a novel unbiased pedigree-based strategy that identifies double-mutants who harbor an AD disease mutation and simultaneously carry haplotypes encoding the modifier.

Methods: We studied a French-Canadian AD glaucoma pedigree in which 154 heterozygotes (HTZ) carry the MYOC ^{K423E} mutation. Diagnoses ranged from juvenile OAG to late adult-onset POAG. Ages-at-onset (AAO), defined as age at which intra-ocular pressure ≥ 22mm Hg, ranged from 7 to > 60 y old. Several asymptomatic HTZ aged > 55 y old were also observed. Using the pedigree, we mapped a modifier locus for extreme variability of AAO at 20q13. It was named Modifier of Glaucoma 1, MOG1. To find reliable gene-gene interactions in humans, we developed a novel unbiased pedigree-based strategy. It was named DIGGI for Double-mutants that participate In Gene-Gene Interactions.

Results: DIGGI is a two-stage algorithm that exploits datasets obtained with diverse types of markers that can be coded, like microsatellites, VNTRs, SNPs and CNVs. The 1^{st} stage is the identification of MOG1 alleles, or marker haplotypes, associated with the modifier. The 2^{nd} stage is the identification of double-mutants who simultaneously carry the primary disease mutation and show higher contrasting ages at onset when compared to the AAO of individuals who are within their neighborhood (kinship coefficient defined as $\Phi(X,Y) \geq 0.0625$ where X and Y are people closer or equal to first degree cousins) and carry the myocilin K423E mutation. Robust double-mutants are positioned at the extremes of the extremes contrast distribution of the AAOs within their neighborhood. Simulation and statistical studies show that DIGGI is reliable at selecting unequivocal double-mutants that participate in gene-gene interactions.

Conclusions: We successfully applied to the case of glaucoma modifier gene a powerful strategy to identify family members who share common modifier haplotypes associated with specific endophenotypes for quantitative traits. These double-mutants will be used to characterize the MOG1 modifier.

TITLE: Effectiveness and Safety of Resident-Performed Simultaneous Bilateral Selective Laser Trabeculoplasty in Patients With Open-Angle Glaucoma

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Si, M. Qiu, Ophthalmology, University of Chicago Division of the Biological Sciences, Chicago, Illinois, UNITED STATES|J. Xiao, University of Chicago Pritzker School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Zhuangjun Si: Commercial Relationship: Code N (No Commercial Relationship) | Jason Xiao: Commercial Relationship: Code N (No Commercial Relationship) | Mary Qiu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While its pathophysiology is not fully understood, there are a number of genetic and clinical risk factors associated with glaucoma; the primary risk factor is elevated intraocular pressure (IOP). Laser trabeculoplasty is a widely-used treatment method for glaucoma because it effectively reduces IOP without bearing the greater risks of invasive surgery. Selective laser trabeculoplasty (SLT) is a core competency skill that ophthalmology residents learn; however, competency in SLT is not well-defined, as experience in glaucoma procedures is variable by program. SLT is typically performed one eye at a time. During the COVID-19 pandemic, in-office visits were minimized and surgeries were limited to only the most vision-threatening at the University of Chicago. Bilateral SLT on the same day was used to keep IOP controlled during this period, while patients could not be monitored as frequently and surgeries were postponed. The goal of this study is to assess the effectiveness and safety of same-day bilateral resident-performed SLT in comparison to reported statistics of attending-performed SLT in the literature.

Methods: A retrospective chart review of patients who underwent simultaneous bilateral SLT between January 2019-May 2021 was performed to quantify the effectiveness and safety of the procedure compared to published rates in the literature. Specifically, we examined the intraocular pressure (IOP) at the visits before and after the SLT procedure, type of glaucoma diagnosis, Age, Sex, and complications (IOP elevation, iritis, macular edema).

Results: Preliminary data included a total of 51 patients (of which 32 were female) and 108 eyes (3 patients underwent SLT twice). Average age was 66. Average IOP was 18.7 mmHg (SD 5.0) on visit prior to SLT and 17.6 (SD 6.5) on day of SLT with the average IOP decreasing to 15.9 (SD 5.0) and 15.7 (SD 4.5) on the first and second follow-up. There were 2 patients in whom we documented IOP spikes on the visit after SLT was performed, one of whom had documented compliance issues on multiple visits. No macular edema or iritis was noted.

Conclusions: We found a similar rate of decrease in IOP after bilateral SLT by residents compared to prior studies by attending physicians with very few complications. Resident-performed simultaneous bilateral SLT appears to be an effective and safe option for IOP-lowering.

ABSTRACT BODY:

Purpose: Irreversible vision loss from primary open-angle glaucoma (POAG) can be prevented through timely diagnosis and treatment, although definitive diagnosis can be difficult in early-stage disease. As a consequence, large numbers of glaucoma suspects require regular monitoring, even though many low-risk suspects may never develop disease, and other high-risk suspects may have delayed or inadequate treatment. Given that POAG is one of the most heritable common diseases, unique opportunities exist to employ genetic instruments in risk-stratified screening, diagnosis and treatment of early glaucoma.

Methods: Here we assessed the impact of glaucoma polygenic risk on early glaucoma progression, using clinical and genetic data from a prospective longitudinal cohort study in individuals of predominantly European ancestry (PROGRESSA). A total of 1,605 eyes from 829 early manifest glaucoma cases or glaucoma suspects had sufficient data for visual field progression analyses using serial 24-2 Humphrey visual fields, with a glaucoma polygenic risk score (PRS) derived from genotyping array data on all 829 participants.

Results: Individuals in the top 5% glaucoma PRS risk group were at a higher risk of visual field progression compared to the remaining 95% after 5 years (HR 1.5, 95%CI 1.13–1.97, P=.005). Conversely, those in the bottom 20% PRS risk group were at a lower risk of visual field progression compared to an intermediate risk group over 3 years (HR 0.52, 95% CI 0.28–0.96, P=.038).

Conclusions: High polygenic risk was associated with more rapid visual field progression in early manifest glaucoma cases and glaucoma suspects. A PRS may serve as a valuable adjunct to identify individuals who stand to benefit the most from more frequent surveillance, and earlier or more intensive treatment.

ABSTRACT BODY:

Purpose: Models that can quantify and predict geographic atrophy (GA) growth would provide valuable insights to the design and efficacy of clinical trials. This work aims to develop learning-based prediction models for accurate GA estimation at variable timepoints using patient demographic and image-based variables.

Methods: As part of the Age-Related Eye Disease Study 2 (AREDS2) clinical trial, data was collected from 890 participants (comprising 1215 eyes and 3411 study visits, spanning 1-4 yrs) who exhibited prevalent or incident GA. Color fundus photographs were graded for GA area, involvement and proximity to center, and GA configuration. Patient demographic information (i.e., age, race, gender, smoking status) was also collected. Random forest (RF) regression models were developed to predict GA growth rates using demographic and image-based predictor variables. Predictions were made for growth rates computed at 1 year (3296 pairs), 2 year (2215 pairs), 3 year (1361 pairs), and 4 year time intervals (719 pairs) and after combining data from all time spans. The performance was quantified using RMSE and correlation coefficient (R^2) in a ten-fold cross-validation setting.

Results: Growth rates measured using GA areas at different timespans were (mean ± stdev) 0.31 ± 0.43 mm/yr over 1 year, 0.29 ± 0.28 mm/yr over 2 years, 0.28 ± 0.22 mm/yr over 3 years, and 0.27 ± 0.19 mm/yr over 4 years. The average growth rate measured using all time intervals was 0.29 ± 0.33 mm/yr. The RF prediction model estimated growth rates with RMSE = 0.43 mm/yr (R^2=-0.01) over 1 year, 0.26 mm/yr (R^2=0.09) over 2 years, 0.20 mm/yr (R^2 =0.15) over 3 years, and 0.18 mm/yr (R^2=0.10) over 4 years. After combining growth rates measured across different time spans, the RF model exhibited RMSE = 0.30 mm/yr (R^2=0.05). Both measured growth rates and errors of the prediction models decreased with increasing measurement time-intervals.

Conclusions: At longer time-spans, both GA growth rate variability and learning-based prediction accuracy worsened gradually. At shorter time-spans, measurement error could constitute a larger portion of the growth rate and could result in higher variability and more challenging estimation by prediction models. Future work investigates additional automated image-derived metrics to improve the prediction accuracy.

ABSTRACT BODY:

Purpose: Myt1L is a zinc finger transcription factor expressed by a variety of neuron types. In the cerebral cortex, Myt1L counteracts Notch signaling to promote differentiation of neural progenitors and repress non-neuronal fates. Interestingly, it is one of three transcription factors, in combination with Brn2 and Ascl1, capable of inducing reprogramming of fibroblasts into functional neurons. Here we investigate possible functions of Myt1L in retinal development, which have not been previously reported.

Methods: Tissue was collected from CD1 mice at the indicated developmental time points, and retinas were stained with a MYT1L guinea pig polyclonal antibody (Guoqiang Gu, Vanderbilt University). GFAP-Cre and R26 reporter mice were obtained from JAX. The indicated plasmids were injected subretinally into CD1 mouse pups at P1, electroporated with 5x80V pulses, and retinas were collected for analysis at P21. Imaging was performed on a Zeiss LSM700 confocal microscope.

Results: We find that MYT1L is absent from progenitors, but is present in postmitotic neurons starting as early as E15.5, and well into adulthood (Figure 1A-F). It is most highly expressed by retinal ganglion cells, but is also detected at lower levels in amacrine and bipolar cells, based on co-localization with BRN3A, PAX6 and CHX10 (data not shown). In contrast, Müller glial cells do not express Myt1L, as demonstrated by lack of overlap with GFAP-Cre;R26-tdTom (Figure 1G-K). Interestingly, overexpression of Myt1L in postnatal retinal progenitors was sufficient to strongly repress generation of Müller glia. In control experiments, 56.5% ± 8.4% of electroporated cells in the INL were SOX9-positive Müller glia (Figure 1L-O), compared to only 20.9% ± 3.0% in Myt1L overexpression experiments ($p < 0.01$).

Conclusions: Taken together, our results indicate that Myt1L is expressed by retinal ganglion cells, amacrine cells, and bipolar cells during development, and that it can strongly repress generation of Müller glia by postnatal retinal progenitors.

TITLE: A Comparison of OCT Angiography Non-Perfusion Area Measurements Made With a Rules-Based Approach and Artificial Intelligence

SESSION TITLE: AI in Retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Hormel, Y. Guo, T.S. Hwang, D. Huang, Y. Jia, Oregon Health & Science University, Portland, Oregon, UNITED STATES|J. Wang, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Tristan Hormel: Commercial Relationship: Code N (No Commercial Relationship) | Jie Wang: Commercial Relationship(s);Code P (Patent):Optovue | Yukun Guo: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Hwang: Commercial Relationship: Code N (No Commercial Relationship) | David Huang: Commercial Relationship(s);Code F (Financial Support):Optovue;Code P (Patent):Optovue;Code R (Recipient):Optovue | Yali Jia: Commercial Relationship(s);Code F (Financial Support):Optovue;Code P (Patent):Optovue, Optos

ABSTRACT BODY:

Purpose: To compare optical coherence tomography angiography (OCTA) non-perfusion area (NPA) measurements made using artificial intelligence (AI) and a traditional rules-based approach.

Methods: NPA measurements were performed on eyes with diabetic retinopathy (DR), with severity determined by a central reading center based on 7-field color fundus photography using the early treatment of diabetic retinopathy (ETDRS) scale (referable ≥ 35; vision-threatening ≥ 53). We assessed the accuracy of DR diagnosis based on NPA measurements made with each approach by calculating the area under receiver operating characteristic curve, and the robustness of each method by measuring repeatability and the effect of signal strength. Measurements were assessed using 959 OCTA scans of eyes diagnosed with DR (2 non-referable; 670 referable/non-vision threatening; 287 vision threatening). The source of the data is the DRCR Retina Network, but the analyses, content and conclusions presented herein are solely the responsibility of the authors and have not been reviewed or approved by DRCR Retina Network. 15 repeat scans in this dataset were used to test repeatability. Since the DRCR dataset did not contain healthy controls, 128 healthy eyes imaged at Oregon Health & Science University (OHSU) were added to assess NPA-based diagnostic accuracy. The two methods considered here are 1) a rules-based approach that determined NPA using a vessel distance map, and 2) an AI-based approach that used a U-net-like architecture (Fig. 1). Both approaches quantified NPA in the superficial vascular complex and inner retinal slab. The AI model was trained with a separate dataset from OHSU containing 492 scans of eyes with varying degrees of DR.

Results: The AI approach had better diagnostic performance than the rules-based method for referable vs. non-referable DR (Fig. 2). The AI-based NPA measurements were also less correlated with signal strength in the SVC (R^2 = 0.121 rules-based vs. R^2 = 0.002 AI-based). The rules based approach achieved slightly higher repeatability in the SVC (intraclass correlation coefficient = 0.945 rules-based vs. = 0.923 AI-based methods).

Conclusions: NPA measurements made on a clinical dataset using an AI-based approach have a higher diagnostic accuracy for diagnosing referable DR and are more robust with respect to scan quality than NPA measurements from a rules-based approach.

TITLE: Novel lipid nanoparticle variants for in-vivo mRNA delivery to photoreceptors

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Gautam, G. Sahay, Department of Pharmaceutical Sciences, College of Pharmacy, Oregon State University, Portland, Oregon, UNITED STATES|R.C. Ryals, G. Sahay, Department of Ophthalmology, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Milan Gautam: Commercial Relationship: Code N (No Commercial Relationship) | Renee Ryals: Commercial Relationship: Code N (No Commercial Relationship) | Gaurav Sahay: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although lipid nanoparticles (LNPs) effectively deliver genes to the retina, most of the gene expression is still limited to the retinal pigmented epithelium (RPE) and Müller glia. This study tested the hypothesis that modifications to LNPs can steer LNP delivery of mRNA to the photoreceptors. Successful gene delivery to RPE, Müller glia, and photoreceptors expands the utility of LNPs for treating inherited retinal degenerations.

Methods: LNP variants were prepared via rapid microfluidic mixing of an organic phase containing lipids and an aqueous phase containing mRNA. The organic phase, consisting of ionizable lipid, DSPC, sterols, DMG-PEG, and PEGs at different molar ratios, was rapidly mixed with the aqueous phase having Cre or mCherry mRNA in the citrate buffer pH 4.0. LNPs were characterized for hydrodynamic radius and polydispersity index (PDI) using dynamic light scattering (DLS) and mRNA encapsulation efficiency using a modified Quant-iT RiboGreen RNA reagent. First, LNPs were evaluated for transfection efficiency in multiple cell lines. Then, Cre or mCherry mRNA (300 ng) was delivered via subretinal injections in both Ai9 and NRL-GFP mice. Live in-vivo retinal imaging and immunohistochemistry (IHC) of retinal sections were performed to characterize the intracellular gene expression.

Results: Novel LNPs had a diameter of < 80 nm with a < 0.13 PDI. The zeta potential (ZP) of the particle varied depending on the functional PEG. The ZP of LNPs without functional PEG was -0.95±0.6. In all cases, encapsulation efficiency was higher than 96% with a spherical shape in morphology. LNP variant had significantly higher transfection efficiencies compared to standard LNPs in photoreceptor cell lines. After delivery of LNP variants in Ai9 mice, robust and selective tdTomato expression was observed using fundus imaging. IHC confirmed expression in the photoreceptors and RPE. With the addition of b-sitosterol, expression was observed in Müller glia as well. At 48 h post-injection, mCherry protein expression was localized to the RPE and Müller glia in NRL-GFP mice, further strengthening our observation.

Conclusions: LNP-based mRNA delivery has largely been restricted to the RPE. We have now demonstrated that LNP variants can deliver genes to the photoreceptors, and the RPE, thus opening the scope for treatments against inherited retinal degenerations.

TITLE: Retinal incorporation and turnover of bis-allylic deuterated docosahexaenoic acid (D-DHA) - a new dry AMD drug candidate: a comprehensive tissue uptake and elimination survey and comparison between murine ocular and related body tissues

SESSION TITLE: AMD and diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. James, Nutritional Sciences, The University of Texas at Austin, Austin, Texas, UNITED STATES|

Commercial Relationships Disclosure: Genevieve James: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retina and surrounding tissues are vulnerable to oxidative damage due to a unique combination of direct light exposure, their high rate of oxidative metabolism, and the high content of the fatty acid DHA. Deuteration at the bis allylic positions dramatically increases the resilience of DHA in vitro and in vivo. We studied the increase and washout kinetics of orally consumed D-DHA in mice over several months to understand how it is incorporated and removed from target tissues.

Methods: At 12 weeks of age, mice were placed on a diet with 0.5% D-DHA for 78 days, then switched to an identical diet with normal H-DHA. Animals were sacrificed periodically, and tissues were collected. Lipids were extracted, converted to fatty acid methyl esters, and analyzed by high-resolution gas chromatography chemical ionization mass spectrometry to quantify the relative proportions of D-DHA and H-DHA, expressed at D-DHA as a % of total DHA in the relevant pool, the key figure of merit for drug efficacy. Doubling time and half-lives were calculated by least-squares fitting to single exponential models.

Results: D-DHA rose more rapidly in RPE-choroid/Sclera than in the neural retina or optic nerve. By day 78 D-DHA was over 90% in all tissues. RPE-choroid/Sclera and retina had more similar washout curves. Doubling times and half-lives were 20-22 days for both retina and optic nerve. Doubling time for RPE-choroid/Sclera and liver were similar at about 9 days, while half-lives were 18 and 14 days, respectively, for these two tissues.

Conclusions: The therapeutic threshold for D-DHA efficacy is considered to be about 20%. Retina reached that level by 8 days of feeding. The vascularized RPE-choroid doubling time was at about 40% D-DHA by 8 days similar to the liver. We conclude that D-DHA rapidly crosses the blood-retina-barrier and enters visually active tissues just as its natural DHA parent and may offer protection against oxidative lipid peroxidation.

ABSTRACT BODY:

Purpose: Seniors with low vision underutilize mobile applications (apps) for visual assistance despite their use of smartphones and/or tablet devices. Mobile apps can be a low cost, accessible form of visual assistive equipment for this population, but training is indicated for most to learn to use such apps. We explored which low vision subjects were proficient with these technologies following training.

Methods: 50 adults aged 55+ (mean 72 years; SD ±10; range 55-92) with low vision (VA 20/40-20/800 or legally blind due to visual field) who were naïve to three visual assistive apps (SuperVision+, Seeing AI, Aira) were randomized to receive one-on-one training with one app on a loaner iPhone SE as part of the Community Access through Remote Eyesight (CARE) clinical trial. Subjects' proficiency with the smartphone and app was assessed by the study team after the 1st training session and again at 2-weeks. Multivariable logistic regressions examined potential predictors of app proficiency at the end of the 1st and 2nd sessions. Subjects' race was primarily white (64%), 44% were female, most had macular degeneration (30%) and their own smartphone (84%).

Results: Mean training time was 0.95 hours (SD± 0.44) for the 1st session and 0.43 hours (SD± 0.81) for the 2nd. 48% of subjects were not proficient at the end of the 1st training session, while 39% still lacked proficiency at 2-weeks. Age was a significant predictor of app proficiency, as older subjects were significantly less likely to be proficient after training one (OR: 0.92, 95% CI: 0.85-0.99, p=0.02) and training two (OR: 0.87, 95% CI: .77-.98, p=0.02). Other factors (binocular logMAR visual acuity, randomized app, and duration of the training session) were not significantly related to app proficiency (all p>0.10).

Conclusions: Many older adults with low vision required multiple, lengthy training sessions to become adept at using a new visual assistive app. This suggests that those working in low vision rehabilitation may need to plan for several visits to enable this population to become successful with smartphone apps, especially for the oldest patients.

ABSTRACT BODY:

Purpose: Blue light induced photooxidative stress (BLD) is an established model of advanced geographic atrophy observed in patients with dry AMD. 5-HT1A agonists have demonstrated neuroprotection in rat BLD studies and other mouse CNS injury models. The purpose of this work was to evaluate the 5-HT1A agonist tandospirone (tando) to provide protection in the mouse BLD model, and to measure cytokine production in the Balb/C mouse retina at 1-7 days after light exposure.

Methods: Male, 10-14 week old Balb/C mice: Group 1 daily subcutaneous injections of vehicle, 5 or 10 mg/kg tando on Day -2 to Day 2, N=5. Group 2 no treatment and were sacrificed at 1, 3 and 7 days post light exposure. N=6. Group 3 no treatment no light exposure, N=6. Group 1 and 2 animals were dark adapted overnight and on Day 0 exposed to 19-21 klux of spectrally filtered blue light for 4 hours. Prior to sacrifice all animals received electroretinograms (ERGs) to assess retinal function, and retinal damage was evaluated with OCT imaging. Eyes were collected from Group 2 and 3 and the cytokines IFNg, IL-1b, IL-2, -4, -5, -6, -10, -12p70, KC/GRO and TNFa were measured using the Mesoscale Discovery system.

Results: ERG amplitudes and retinal thickness was significantly reduced 50-70% in vehicle and the 5 mg/kg tando treated animals compared to Group 3. Animals treated with 10 mg/kg had a ~30% decrease in ERG amplitude and retinal thickness which were significantly better than vehicle treated. IL -2, -4, -12p70 and IFNg were below the lowest limit of quantification. Compared to Group 3, there was a non-significant increase of IL-5 from 1.4 to 1.7, IL-6 from 89.8 to 261.4, KC/GRO from 90.6 to 284.1 and TNFa from 62.5 to 102.7 pg/ml at Day 7 post light exposure and little change at Day 1 or Day 3. There was a non-significant decrease of IL-10 from 2.1 to 0.6 pg/ml at Day 3 post light exposure and little change at Day 1 or Day 7. There was a significant increase of IL-1b from 6.9 to 36.5 pg/ml at Day 7 post light exposure and little change at Day 1 or Day 3.

Conclusions: The 5HT1a agonist tandospirone is a viable positive control for drug discovery at 10 mg / kg in Balb/C mice. Up to 7 days post exposure the cytokines measured are insignificant other than IL-1b, which has been demonstrated to be upregulated in other models of retinal pigmented epithelial cells and photoreceptor cells damage.

TITLE: Simultaneously extracted Pattern ERG and VEP responses to visual hemifields using bideconvolution averaging (BiCLAD)

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Ozdamar, J. Bohorquez, Biomedical Engineering, University of Miami, Coral Gables, Florida, UNITED STATES|H. Korkusuz, SUNY Downstate Health Sciences University, New York City, New York, UNITED STATES|J. Toft-Nielsen, JORVEC, Florida, UNITED STATES|

Commercial Relationships Disclosure: Ozcan Ozdamar: Commercial Relationship(s);Code I (Personal Financial Interest):JORVEC | Jonathon Toft-Nielsen: Commercial Relationship(s);Code E (Employment):JORVEC | Hazal Korkusuz: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Bohorquez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Continuous Loop Averaging Deconvolution (CLAD) technique is used to extract "per-stimulus" responses at stimulation rates that normally produce steady-state (SS) responses with conventional methods. This is accomplished by presenting specially designed narrow jitter stimulation sequences (Ozdamar et al., 2014, Toft-Nielsen et al., 2014). In this study, a new bideconvolution (BiCLAD) method employing two temporally jittered biorthogonal sequences to stimulate two visual fields and allow the extraction of independent responses from each hemifield was used.

Methods: Transient (TR) and quasi-steady-state (QSS) pattern PERG-VEPs were recorded at two reversal rates (2.5, 12.5rps) from normal subjects under monocular and binocular conditions. Pattern stimuli were delivered on a rectangular field (28°x14°) made of 2 separate LED based displays. Stimuli were composed of 6 horizontal cycles (99% contrast). Subjects were asked to fixate along the center horizontal line on one of five fixation points. Display subunits were driven either synchronously (monofield) or asyncronously (bifield) with similar mean rates. Conventional TR and BiCLAD deconvolved PERG (N35, P50; N95) and VEP (P60; N75; P100; N135) components were analyzed using latency/amplitude measures.

Results: Both reversal rates produced clearly distinquishable PERG and VEP waveforms with conventional components at all different gaze fixation and eye stimulation conditions. In both monocular and binocular conditions, nasal and temporal PERG responses showed small and consistent differences in amplitude and morphology. Nasal responses resembled a conventional PERG response, while temporal responses exhibited slightly bifurcated and smaller peaks. In the 12.5 rps VEP, the early positive peak (P60) was more prominent and showed binocular summation characteristics and the P100 component was of smaller amplitude. In bifield mode both PERG and VEP components showed lateralization with respect to eye fixation.

Conclusions: Hemifield testing using BiCLAD reveals differences in temporal and nasal morphology and will help in exploring retinal topography and enhancing the diagnostic utility of the PERG in retinal disorders. Simultaneuous VEP testing will further clarify contributions of the visual pathway and cortical areas, helping in stroke and other disorders involving localized trauma to specific cortical regions.

ABSTRACT BODY:

Purpose: To report the frequency of bacillary layer detachment (BLD) and its associations with clinical and visual function outcomes of patients with Vogt-Koyanagi-Harada disease (VKHD).

Methods: Retrospective analysis of 33 patients with VKHD followed for a minimum one year since the acute disease onset with systematic clinical, multimodal imaging and visual function evaluations. All patients were treated with high-dose systemic corticosteroid; 23 patients had additional oral azathioprine. Three independent retina specialists read the images obtained in the spectral domain-OCT (Heidelberg Engineering, Heidelberg, Germany) at baseline (M0) and at the 1^{st}, 3^{rd}, 6^{th}, 9^{th} and 12^{th} months. Frequency of BLD was analysed for its association with other OCT findings, clinical and visual outcomes. Generalized estimating equations (GEE) of binomial distribution and logit link function with interchangeable correlation between eyes and moments were carried out. This study was approved by Institutional Ethics Committee and followed Helsinki declaration.

Results: Included patients (29 female/ 4 male) had a median age of 33 years (15 to 67 years) with a median disease duration of 67 months (27 to 121 months). The median initial visual acuity (VA) was 1.8 logMAR (0 to 2.3 logMAR), 0.2 logMAR (0 to 2 logMAR) at M1 and 0 logMAR (0 to 0.7 logMAR) at M12. Sunset glow fundus (SGF) was seen in 42 eyes (63%) and subnormal full-field electroretinogram (ffERG) was seen in 76% of eyes (47/62) in M12. BLD was present in 87.5% (49/56) of eyes at M0 and in 3% (2/66) at M6 and M9. BLD resolution time was longer compared to serous retinal detachment (SRD) with medians of 1 month (0 to 12 months) and 0 month (0 to 9 months), respectively (Figure). Significant associations were observed between BLD in M1 with worse VA in M0 (median 1.8 vs 1 logMAR; p=0.016); worse VA (median 0.25 vs 0.05 logMAR; p=0.014), worse fluorescein angiography scores (9 vs 5; p=0.002) and indocyanine green angiography scores (15 vs 10.5p= 0.007) in M1; severe fundus (p=0.008), SGF (p=0.006), fibrosis (p=0.005), chorioretinal atrophy (p=0.008), and subnormal ffERG (p=0.045) in M12, as well as longer elipsoid zone resolution time (median 12 vs 3 months; p=0.006) (Table).

Conclusions: Our data pointed out the presence of BLD in M1 as a potential biomarker of a worse prognosis in VKHD, as evidenced by changes in fundus and visual function at 12 months.

ABSTRACT BODY:

Purpose: OLT1177 (Dapansutrile) is an effective inhibitor targeted nucleotide-binding domain leucine-rich repeat and pyrin domain containing receptor 3 (NLRP3) inflammasome. Here we aimed to explore therapeutic effect of OLT1177 in oxygen-induced retinopathy (OIR) model and its potential mechanism.

Methods: OIR model was induced in C57BL/6J newborn mice and OLT1177 was delivered to pups through intraperitoneal injection at P12. Flat mount immunofluorescence and hematoxylin and eosin staining were used to evaluate retinal pathological neovascularization. Western blot and real time PCR were performed to quantify the levels of NLRP3 and inflammatory factors, including IL-1β and TNF-α. Cell counting kit-8 assay was used to evaluate the proliferation of BV2 cells and HUVECs under the hypoxia condition. Meanwhile, EdU incorporation assay, wound-healing assay, transwell assay and matrigel assay are applied to evaluate the proliferation, migration and tube formation of HUVECs.

Results: OLT1177 administration (100μM) significantly attenuated pathological neovascularization ($p<0.01$) and reduced 30% of avascular area ($P<0.005$). Moreover, OLT1177 reduced aggregation and activation of microglia and leakage of retinal vessels. No significant change was found in the expression of NLRP3，whereas the expression of cleaved caspase-1, IL-1β and TNF-α were differentially decreased. Meanwhile, Immunofluorescence analysis showed NLRP3 co-located with both microglia and endothelial cell. OLT1177 inhibited the proliferation of BV2 cells and HUVECs. And the migration and tube formation of hypoxia-induced HUVECs were inhibited after OLT1177 intervention.

Conclusions: Our study showed that OLT1177 exhibited highly antiangiogenic effects through inhibiting the NLRP3-dependent pathway, suggesting an alternative treatment for RNV.

Theodore Smith: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Subretinal drusenoid deposits (SDD) are currently considered a morphological change to the retina commonly associated with AMD. An association has been made with ARMS2 rs10490924 gene polymorphism and the presence of SDD in AMD. 1 The presence of SDD have also been linked to the high risk vascular diseases (HRVD) of carotid artery stenosis, cardiac valve defect, and cardiac pump defect, possibly due to hypoperfusion of the choroid. 2 These groups have never been compared and our goal is to detect possible phenotype differences to better understand the mechanism and improve management.

Methods: Volume spectral-domain optical coherence tomography (SD-OCT) scans, health history questionnaire, genetic testing and serum samples containing lipid values were obtained for 61 subjects with SDD. Images were categorized into atrophic vs exudative and early vs advanced. We compared 2 subgroups: 1) subjects homozygous for ARMS2 risk alleles (TT) and 2) subjects with HRVD without homozygous ARMS2 risk alleles. Univariate statistics used were chi square for categorical variables and two-tailed t-test for continuous variables.

Results: Of the 61 subjects with SDD, 11 were in ARMS2 group and 24 in HRVD group. Age of presentation for subjects in ARMS2 group was 78.1 yo vs. HRVD group was 83.4 yo (p=0.033). Exudative AMD was found in 3/11 (27%) of ARMS2 group and 0/24 (0%) of HRVD group (p=0.007); geographic atrophy was found in 5/11 (45%) of ARMS2 group vs 7/24 (29%) of HRVD group (p=0.34). Advanced AMD in 8/11 (73%) in ARMS2 Group and 7/24 (29%) in HRVD group (p=0.016). There were no statistically significant differences in subfoveal choroidal thickness (CTh), health history questionnaire and serum lipid levels between the groups.

Conclusions: Our small study suggests that ARMS2 Homozygous risk allele carriers have a different disease profile than SDD phenotype non-carriers. These risk allele carriers develop a more aggressive phenotype at a younger age with exudative AMD and advanced AMD being more common in this group. This suggests subjects with ARMS2 associated SDD have a different natural history and prognosis than those with systemic vasculopathy associated SDD.

ABSTRACT BODY:

Purpose: Deep learning of optical coherence tomography (OCT) may help discriminate glaucomatous eyes from healthy controls. However, the underlying decision making processes remain unclear. Recently, through computing class activation maps, our feature agnostic artificial intelligence of OCT images using a 3D convolutional neural network identified the optic nerve head (ONH) and its surrounding regions as structures significantly associated with glaucoma classification (PMID: 31260494). To pursue their contributions further, here we analyzed the optic nerve morphology from OCT and magnetic resonance imaging (MRI) in a subset of glaucoma and healthy subjects.

Methods: Nine early glaucoma, 12 advanced glaucoma, and 4 healthy control subjects underwent spectral-domain OCT at 30x30x2 μm^3 and 3-Tesla anatomical MRI at 1x1x1mm^3. Maximum intensity projection was applied to en-face OCT scans at the ONH (Fig. 1). The areas of the ONH [inner regions of interest, (ROI)] and surrounding regions (outer ROIs) visible in OCT were measured using global thresholding in ImageJ. One-way ANOVAs with post-hoc Tukey's tests were performed on the inner and outer ROIs between the 3 groups. Also, a Pearson correlation analysis was performed between the ROI areas in OCT and optic nerve volume extracted from MRI between the eye and optic chiasm.

Results: For OCT of the ONH, significant group effect was observed for the areas in the inner ROIs (ANOVA: F= 7.823, p=0.00133). Post-hoc analyses revealed a significant difference between healthy controls and advanced glaucoma (p=0.0082) and between early and advanced glaucoma (p=0.0057) but no significance between healthy controls and early glaucoma (p=0.80) (Fig. 2A). No significant group effect was observed in the outer ROIs (ANOVA: F=0.004, p=0.996) (Fig. 2B). There was a negative correlation between the inner ROI area in OCT and optic nerve volume in MRI (R=-0.47, p=0.0011) (Fig. 2C).

Conclusions: The ONH tissues visible on OCT appeared to contribute more than their surrounding regions to distinguishing between glaucomatous eyes and healthy eyes. The negative correlation between ONH area in OCT and optic nerve volume in MRI suggested the need to further understand the interactions between ONH and deeper brain structures in glaucoma.

ABSTRACT BODY:

Purpose: Electroretinography (ERG) remains an underutilized clinical diagnostic tool due to high device cost, complex testing procedures, and strict facility requirements. We performed a proof of concept study to explore the feasibility of a wearable medical device that isolates each eye independently while performing clinical grade ERG testing with the goal of decreasing per-procedure cost, time, and facility requirements in order to expand access to ERG testing.

Methods: Device components were designed virtually using Computer Aided Design (CAD) software and 3D printed with black polylactic acid (PLA) thermoplastic polyester. Eye-pieces were made of polyurethane foam and designed for independent eye isolation from all environmental light. Red, green, blue, white, and infrared (IR) LEDs stimulate the retina and illuminate the IR camera. Light intensity is controlled via current and voltage regulators as well as pulse width modulation (PWM). Light stimulus duration is controlled via LED drivers. IR cameras dynamically measure pupil diameter and digitally adjust light intensity using PWM. A phototransistor measures the light stimulus being presented to each eye. EasyEDA and JLCPCB were used for printed circuit board (PCB) design and manufacturing. User interface, testing procedures, and image processing were programmed using a Raspberry Pi 4 and Python. Light intensity calibration was performed using a factory calibrated Internation Light Technologies 2400 Optical Meter. Pupil measurement calibration was performed using known diameter standards and validated on members of the research team.

Results: See attached photos of prototype goggle device with attached LED control board as well as IR picture of eye with pupil measurements. The pupil measurement software was accurate within 2.5% relative to standard controls ranging from 4-26 mm. The estimated cost of this device, not including labor or excess materials, is $450.

Conclusions: This rudimentary prototype is a preliminary proof-of-concept for a wearable ERG-device that reduces the cost, time and facility burdens associated with clinical ERG testing. Such a device would be particularly useful for early detection and monitoring of chronic disease states, such as diabetic retinopathy. Future directions include device fit optimization and incorporating skin electrodes and appropriate electrical amplifiers to measure the retinal response to light stimulation.

ABSTRACT BODY:

Purpose: Rotenone is a mitochondrial toxicant known to induce neurodegeneration, however, the neuroinflammatory progression has not yet been clearly characterized. As resident immune cells of the central nervous system, microglia are known to enhance the neurotoxicity of rotenone. We postulated that non-invasive imaging of the retina can reveal neurotoxic effects intravitreal injection of rotenone and correlate the phases of the neuroinflammatory progression.

Methods: We monitored the spatial and temporal changes in retina inflammation and neurotoxicity following direct exposure to rotenone by intravitreal injection, by combining imaging techniques including optical coherence tomography (OCT) and confocal scanning-laser funduscopic (cSLO). To visualize microglia activation, we used $Cx3Cr1^{eGFP}$ transgenic mice in which macrophages express green fluorescent protein. Accordingly, we utilized a non-invasive imaging protocol to assess neurotoxicity longitudinally, without an invasive biopsy (Fig1). The OCT images were processed to characterize and quantify rotenone-induced changes in retinal morphology.

Results: We found that a 0.3µL of a 10mM concentration of rotenone caused retinal thinning and neurodegeneration, during the late phase of inflammation. Retinal thinning at day 7 correlated to the first appearance of hyper-florescent puncta in the photoreceptor layer. Furthermore, the puncta proliferated at day 14, indicating lipid peroxidation. The Cx3Cr1 microglia, at day 7 post treatment (Fig 2), were aligned with the nerve fiber tracts (arrow). Before 7 days, microglia activation in the inner portion of retina was not detected. Based on the OCT findings, neurodegeneration was 7-14 days post-injury, and photoreceptor loss was not evident until day 14.

Conclusions: These studies showed a predominantly M1 verses M2 microglia phenotype at 7 days, suggesting transition into chronic inflammation rather than a resolving phase. These studies also indicated that a low dose of rotenone can facilitate development of a neurodegenerative pathology over time, and that the late phase M1 microglia activation may be the driving force of the delayed response and subsequent neurodegeneration. Furthermore, we believe that the non-invasive imaging used in the current study provides a novel approach for characterizing the inflammatory progression of neurotoxicity.

ABSTRACT BODY:

Purpose: Repeated intravitreal injections with vascular endothelial growth factor (VEGF) inhibitors constitute current standard treatment for neovascular age-related macular degeneration (nAMD). However, two thirds of patients are either partial or non-responders to standard treatment, and new treatment modalities harbouring the potential to target multiple pathways are needed.

We have designed multigenic vectors incorporating intron-embedded double Dicer-independent short hairpin RNA (agshRNA) with potent VEGF knockdown followed by an antiangiogenic gene. However, analysis has revealed mis-splicing leading to low expression of the downstream gene. By eliminating potential competing splice sites, we hypothesized that downstream gene expression could be significantly increased.

Accordingly, this study aimed to eliminate mis-splicing by designing intron-embedded agshRNAs without potentially competing splice sites and to increase downstream gene expression in vitro.

Methods: Using the NetGene2 server for splice site prediction and mFold for RNA secondary structure prediction, we designed new constructs predicted to eliminate problematic splice sites. For easy validation, green fluorescent protein (GFP) was inserted downstream of the agshRNA-containing cassette, and fluorescent microscopy, flow cytometry and RT-PCR with sequencing of amplicons were used to investigate splicing of the agshRNA construct and GFP expression. All experiments were performed in HEK-293 cell lines.

Results: Fluorescent microscopy and flow cytometry showed a significant increase in downstream GFP expression, and RT-PCR with amplicon sequencing confirmed correct splicing.

Conclusions: By eliminating predicted aberrant splice sites in our agshRNA-containing cassette, we corrected splicing and thereby increased downstream GFP expression, paving the way for inserting therapeutic proteins with the aim of developing efficient and persisting therapy for patients with nAMD.

ABSTRACT BODY:

Purpose: Dietary glycemic index (GI) indicates how fast glucose from dietary carbohydrates enters the bloodstream after consuming a food item. Dietary GI has been found as a risk factor for developing blinding diseases, such as age-related macular degeneration and cataracts. The retinas of mice fed a high GI diet for 12 months show photoreceptor loss, which is accelerated in Nrf2 knockout mice. To assess the molecular consequences of GI in WT and $Nrf2^{-/-}$ mice, we have evaluated transcriptomic changes in the retinas and livers after exposure to a high (HGI) or low glycemic (LGI) diet.

Methods: C57BL/6 (WT) and $Nrf2^{-/-}$ mice were aged from 6 to 18 months while feeding on an LGI diet of 70% amylose + 30% amylopectin or an HGI diet of 100% amylopectin. RNA from retinas and livers was used for RNA-seq. Bioinformatic analyses involved the Bioconductor pipeline of edgeR and limma. Differential analysis was set at two fold change and p-value of 0.05, before pathway annotation with gProfiler.

Results: Principal component analysis showed distinct genotype-based clustering among WT and $Nrf2^{-/-}$ livers. WT HGI mice displayed higher expression of glutathione pathway genes, such as glutathione S-transferase, relative to LGI. Notably, glutathione genes were reduced by 2-6 fold in $Nrf2^{-/-}$ livers, regardless of GI, indicating gene-diet interactions. The expression of retinol metabolism genes, including aldehyde dehydrogenase and UDP glucuronosyltransferase, were also reduced in $Nrf2^{-/-}$ livers. Mitochondrial OXPHOS genes, involved in complexes 1 and 5, as well as late endosomal/lysosomal autophagy genes, were upregulated in WT HGI livers but did not show any response to GI in $Nrf2^{-/-}$ livers. Retinal transcriptome analysis is in progress.

Conclusions: The interaction between genetics and dietary GI in WT and $Nrf2^{-/-}$ mice can help explain the differences in phenotype and disease susceptibility. We reason that $Nrf2^{-/-}$ animals experience reduced ability to respond to glycemia-induced stress due to attenuated antioxidant response systems. This leads to a lowered ability to sanitize the cell of damaging molecules. Retinal transcriptomic analysis would reveal a pathmechanistic relationship between GI, genotype, and retinal degeneration.

TITLE: Emergency Ophthalmology Consultations at a Large Tertiary Care Hospital: One-Year Results during the COVID-19 Pandemic in Los Angeles County

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Zukin, Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Leonid Zukin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Across all medical and surgical specialties, the COVID-19 pandemic has had a massive and likely lasting impact on the practice patterns of providers and the behaviors of patients. In ophthalmology, many new technologies, protocols, and recommendations have emerged, including altered triaging patterns and resource allocation. To provide addition data to such quality improvement efforts, this retrospective study examines one year's worth of data on the volume and nature of emergent ophthalmic consultations at one of the largest and busiest hospitals in one of the largest counties in the United States.

Methods: The timing and nature of every new, daily consultation to the ophthalmology service placed from the emergency department at a large tertiary hospital in Los Angeles County was recorded from July 2020 until June 2021. Of note, this data did not include inpatient consultations, outpatient referrals made by other providers, or consults made from the urgent care clinic. Additional data on COVID-19 cases, hospitalizations, and deaths were obtained from resources publicly available online.

Results: During the study period, the ophthalmology service received 4,149 new consults from the emergency department, approximately 12 new consultations daily on average. Interestingly, we found that this volume dropped from October 2020 through February 2021 (down to 8 daily consults in January), coinciding with a peak of COVID-19 cases, hospitalizations, and deaths reported in Los Angeles County over the same timeframe. Further analysis into the consult reason and the urgency of the consults was also performed.

Conclusions: This study utilizes a large ophthalmic data set obtained through the most severe COVID-19 surge in the United States to date. We identified a decrease in consultation volume during a COVID-19 surge and characterized changes in the nature of these emergent ophthalmic referrals during this time.

ABSTRACT BODY:

Purpose: To investigate safety and dose response of subretinally delivered GT005, an investigational recombinant adeno-associated viral (AAV2) vector encoding Complement Factor I (CFI), for treatment of geographic atrophy (GA) secondary to age-related macular degeneration (AMD).

Methods: FOCUS (NCT03846193) is an open-label multicenter study consisting of 4 parts: dose-escalation of GT005 delivered via transvitreal subretinal injection (TVSI), dose-expansion with TVSI, dose-escalation of GT005 delivered using the Orbit subretinal delivery system (Orbit SDS), dose-expansion with the Orbit SDS. All patients had bilateral GA at baseline and received a single subretinal administration of GT005 in the study eye. Primary endpoint is safety of GT005 over 48 weeks, with secondary endpoints including anatomical/functional outcomes and changes in complement protein expression in the vitreous humor. Part 1 explored 3 GT005 dose levels (2E10, 5E10 and 2E11 vector genomes [vg]) delivered via TVSI, Part 2 further explored dose-levels that were shown to be safe and tolerable in Part 1. Interim data from the TVSI cohorts are presented herein

Results: On December 2021, enrolment was complete for Parts 1 and 2 and 31 patients had received GT005 via TVSI, 11 in Part 1 and 20 in Part 2, with a mean follow-up of 51.8 weeks (range: 2.3 to 144.3). At baseline, the mean age was 80.3 years (68 to 93), 71.0% (22/31) were women, and 96.8% (30/31) were white. All 3 dose levels of GT005 delivered via TVSI were well-tolerated, with no dose-related trends in the frequency and type of reported adverse

events (AEs) to date. Of the 48 treatment-emergent ocular AEs in 21 patients, 29 occurred in the study eye only and 10 were bilateral. From the AEs affecting the study eye, majority were mild (30/39) and considered unrelated to GT005 (37/39). From the moderate AEs affecting the study eye (9/39), 5 were related to worsening of cataracts, and 1 described the conversion to choroidal neovascularization. No severe or serious ocular AEs were reported. There were no signs of GT005-related inflammation. Biomarker analysis of vitreous including complement factors at baseline and follow-up will be presented.

Conclusions: GT005 had a positive safety profile at 2E10 to 2E11vg with no signs of GT005-related inflammation.

TITLE: Deamidation in human gammaS-crystallin increases susceptibility to glutathione induced oxidation and aggregation

SESSION TITLE: Lens proteins: normal and pathogenic biochemistry

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.J. Lampi, K. Zientek, S.G. Wheeler, D. Anderson, U.P. Shinde, L.L. David, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Kirsten Lampi: Commercial Relationship: Code N (No Commercial Relationship) | Keith Zientek: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Wheeler: Commercial Relationship: Code N (No Commercial Relationship) | David Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Ujwal Shinde: Commercial Relationship: Code N (No Commercial Relationship) | Larry David: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine whether deamidation of γS-crystallin increases the susceptibility of its 7 cysteines to glutathionylation and disulfide bond formation.

Methods: Recombinantly expressed wild type (WT) human γS-crystallin and a triple mutant (TM) containing D14, D76, and D143 (sites undergoing extensive deamidation in cataractous lenses) were incubated under anaerobic conditions for 5 days in either 5 mM reduced glutathione (GSH), or 2.5 mM oxidized glutathione (GSSG). The overall amount of glutathionylation and disulfide bond formation was determined by whole mass measurement. Trypsin digestions were then performed to support parallel reaction monitoring (PRM) and Skyline software analysis to detect specific sites of modification. Aggregation was detected by measuring dynamic light scattering.

Results: Following incubation, WT γS underwent little glutathionylation and only a single disulfide was detected in 18% of the protein. In contrast, 3% of TM γS contained one disulfide + one glutathionylation, 37% one disulfide, 34% two disulfides, and 4% three disulfides. The PRM analysis of tryptic digests of WT and TM indicated that only the TM contained peptide 19-34 (the peptide containing C22, C24, and C26) with both a disulfide bond and a site of glutathionylation. TM furhter contained increased disulfide bonding between peptide 19-34 and the two peptides containing C36 and C129. Further increased disulfide formation occurred in TM between C36-C114, C82-C114, and C114-C129 compared to WT. PRM analysis indicated that the major oxidized form of WT containing a single disulfide was due to a mixture of one disulfide between C22 and C26, and another between C24 and C36. Dynamic light scattering measured larger aggregates in TM than WT initially with sample loss after 5-day incubation in the TM.

Conclusions: Deamidation increased the susceptibility of γS to oxidation through disulfide exchange reaction with GSSG. This presumable was due to increased conformational dynamics allowing increased exposure and proximity of normally buried cysteines. The locking of TM γS into non-native confirmations due to the resultant disulfide bonds may contribute to increased light scatter. The results support that deamidation and elevation of GSSG in aged lenses may act synergistically to cause cataracts.

ABSTRACT BODY:

Purpose: Anti-vascular endothelial growth factor (anti-VEGF) injection is now the first-line therapy for central-involved Diabetic macular edema (DME). However, the response to anti-VEGF treatment is not predictable. Alternative treatments should be offered to the non-responders as soon as possible to gain earlier and better visual improvement. We developed a temporal convolutional network (TCN) model to predict the change of visual acuity (VA) at one year after 3 monthly anti-VEGF injections using optical coherence tomography (OCT) images at baseline, one- and three-month follow-up visits.

Methods: Serial OCT images from 317 patients who received at least 3 monthly anti-VEGF treatments, had serial OCT images and completed 12-month follow-up at Taipei Veterans General Hospital were retrospectively collected. The treatment effect was defined by the change of VA at 12-month follow-up (final VA) compared with baseline VA. The improved group refers to patients whose final VA improved for over 2 lines at the Snellen chart compared with baseline. The other patients were classified as non-responders. The image dataset was divided into training and testing datasets at a ratio of 5:1. To apply the TCN on image data, a pre-trained model ResNet50 was used to extract the image features, and then fine-tuned by the training dataset. (Figure)

Results: A total of 101 patients were classified as the improved group. Owing to imbalanced data distribution, data augmentation was performed specifically in the improved group. If 3 OCT images concatenated in the channel dimension were used to predict treatment outcome using ResNet50, the predictive accuracy, specificity and sensitivity were 69.04%, 70.37%, and 68.05% respectively. However, if TCN was applied to catch time-series information of the OCT images, the predictive accuracy improved to 81.25%, with a specificity of 74.40% and sensitivity of 92.07%.

Conclusions: Applying TCN to extract serial features of OCT images following anti-VEGF treatment may be a workable architecture to predict visual outcomes following anti-VEGF treatment in DME patients. This approach may help us to identify unresponsive patients who may benefit by switching to steroid treatment or surgical intervention to avoid unnecessary continual anti-VEGF injection.

TITLE: Using Minimum Test Tradeoff to Assess the Value of OCTA for Predicting Moderate to Severe NPDR in Patients with Diabetes Mellitus

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Baker, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Dara Baker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A recent study utilized machine learning (ML) to diagnose nonproliferative diabetic retinopathy (NPDR) based on optical coherence tomography (OCT) alone, OCT in combination with OCT angiography (OCTA), and OCT/OCTA with clinical factors in classifying diabetic retinopathy. The results demonstrated an increase in area under the curve (AUC)s with OCT/OCTA vs OCT with the addition of image analysis and clinical data. The study failed to consider the costs of data acquisition to improve the model. We therefore questioned whether the addition of the OCT/OCTA was worthwhile to improve risk prediction.

Methods: We used decision analysis to compare models based on clinical factors vs those including image analysis. The methodology is based on recent work by Baker, who developed a useful decision-analytic metric, the test tradeoff, and a simple approximation of its minimum value. For a given ratio of the benefit of a true positive to the cost of a false positive, the test tradeoff is the minimum number of data collections per true positive to yield a positive net benefit. We used Baker's formula applied to model comparisons to compute an approximate minimum test tradeoff (over benefit-cost ratios) for an added predictor, MTT.

Results: Inputs included AUCs for ML models using OCT alone (75.6%) versus OCT in combination with OCTA (92.2%). The formula also requires rates of outcome prevalence in the population, which is 14% for moderate and 6% for severe NPDR in patients with known DM. As a baseline for OCT alone, we found MTT = 42 OCTs per true positive prediction of moderate NDPR and MTT= 10 OCTs per true positive prediction of severe NDPR. For OCTA to be worthwhile when added to OCT, we found MTT=54 OCTAs for 1 true positive prediction of moderate NPDR or MTT= 23 OCTAs for 1 true positive prediction of severe NPDR.

Conclusions: Fundoscopic examination remains a vital component of classification and prognosis of diabetic retinopathy to assess for NPDR. Our findings suggest that the addition of OCTA imaging to OCT imaging alone does not yield a net benefit for the additional cost required to diagnose moderate or severe NPDR in a patient with diabetes. Although the monetary cost for adding OCTA per patient may be moderate, the benefit of improved accuracy in diagnosis remains equivocal, as moderate and severe NPDR are often managed conservatively.

TITLE: Evaluation of the association between trachoma and vision-related quality of life using the Pediatric Eye Questionnaire

SESSION TITLE: Pediatric Ophthalmology Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Haseeb, A.R. Djalilian, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|T. Eleiwa, I.A. Elsaadani, R.H. ElSheikh, Department of Ophthalmology, Benha University, Benha, EGYPT|A. Elhusseiny, Department of Ophthalmology, University of Arkansas System, Little Rock, Arkansas, UNITED STATES|

Commercial Relationships Disclosure: Abid Haseeb: Commercial Relationship: Code N (No Commercial Relationship) | Taher Eleiwa: Commercial Relationship: Code N (No Commercial Relationship) | Ibrahim Elsaadani: Commercial Relationship: Code N (No Commercial Relationship) | Reem ElSheikh: Commercial Relationship: Code N (No Commercial Relationship) | Abdelrahman Elhusseiny: Commercial Relationship: Code N (No Commercial Relationship) | Ali Djalilian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the association between trachoma and vision-related quality of life (VR-QOL) in children and their families using the Pediatric Eye Questionnaire (PedEyeQ).

Methods: A prospective case-control study including children less than 18 years of age. Participants comprised 113 children with trachoma and their parents versus 75 healthy age-, gender-, residence-matched children who served as controls and their parents. The trachoma was categorized into follicular trachoma (TF), trachoma intense (TI) and trachomatous scarring (TS).

Results: Of 113 participants with trachoma, 53.1% were boys and 58.4% had rural residence. Child PedEyeQ domain scores were lower with trachoma versus controls and the greatest mean difference was in functional vision (10.3 points; P <0.001). Proxy PedEyeQ domain scores were lower with trachoma with the greatest difference in bothered by Eyes/Vision (14.3 points; P <0.001). Parent PedEyeQ domain scores were lower with trachoma; the greatest difference was in worry about child's eye condition (9.1 points; P <0.001). Subgroup analysis showed that the reduction in PedEyeQ domain scores was more severe in TS followed by TI (P<0.001). Stepwise linear regression analysis revealed that 44 % of the PedEyeQ score could be predicted by the clinical grade of trachoma (P < 0.001). In the trachoma group, a higher clinical grade was associated with lower PedEyeQ domain scores in children, parents, and proxy (P<0.001). The parents' PedEyeQ scores were correlated with their children's PedEyeQ scores (R = 0.6; P<0.001).

Conclusions: These findings suggest trachoma has a negative impact on VR-QOL for children and their parents, especially in children with TI/TS grading.

TITLE: Intraoperative Intravitreal Bevacizumab Prolongs Survival of Trabeculectomy Blebs at 12 months: The Avastin in Trabeculectomy Study

SESSION TITLE: Surgery and Wound Healing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Craig, S. Mullany, J. Landers, Ophthalmology, Flinders Univeristy, Adelaide, South Australia, AUSTRALIA|

Commercial Relationships Disclosure: Jamie Craig: Commercial Relationship: Code N (No Commercial Relationship) | Sean Mullany: Commercial Relationship: Code N (No Commercial Relationship) | John Landers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the effect of adjunctive intraoperative intravitreal bevacizumab injection on trabeculectomy bleb function and structure during the first postoperative 12 months.

Methods: Single centre double-blinded randomised, placebo-controlled trial on 131 patients with glaucoma requiring trabeculectomy.

Intervention: Patients were subjected to a standardised trabeculectomy procedure augmented with onlay MMC 0.04%, and standardised follow-up protocol. Subjects were randomised to receive intraoperative intravitreal injection of either bevacizumab (1.25mg in 0.05ml) or placebo (balanced salt solution; BSS, 0.05ml).

The primary outcome was defined as ‘complete success’ if intraocular pressure (IOP) remained less than a predefined target IOP without the requirement of topical IOP lowering medication, or ‘qualified success’ if additional topical IOP lowering medication was required to meet the predefined target IOP threshold. Secondary outcomes included IOP, requirement for subsequent bleb needling, number of IOP lowering medications, and bleb morphology based on assessment of the trabeculectomy bleb using the Moorfields Bleb Grading Scheme.

Results: Of 131 patients randomised to bevacizumab (n=65) or placebo (n=66), 128 patients completed 12 months of follow up. At one year, 6% of the bevacizumab group failed the definition of complete success, compared with 17% of those in the placebo group (P=0.015). In addition, 2% of the bevacizumab group failed the definition of qualified success, compared with 10% of those in the placebo group (P=0.033). Within the placebo group, IOP and the requirement for bleb needling was higher at one month (P<0.05). Usage of IOP lowering medication was higher at 6-months (P<0.05) and 12-months (P<0.05). Blebs in the bevacizumab group were larger in the central extent (P<0.001), total extent (P<0.01) and height (P<0.001) at one month compared with the placebo group. There was no significant difference in complications between the bevacizumab and placebo groups.

Conclusions: Bevacizumab given as a single intravitreal dose during trabeculectomy surgery results in improved surgical success as 12 months, with a significant reduction in the need for additional medication and bleb needling to achieve target IOP. Furthermore, this intervention results in blebs which are larger and less inflamed.

Valdez-Garcia, Ophthalmology, Instituto Tecnologico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO|

Commercial Relationships Disclosure: Arturo Ramirez-Miranda: Commercial Relationship: Code N (No Commercial Relationship) | Simran Mangwani-Mordani: Commercial Relationship: Code N (No Commercial Relationship) | José Arteaga-Rivera: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Eugenio Valdez-Garcia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the changes of biomechanical properties, endothelial cell density (ECD), higher-order aberrations, and posterior corneal elevation (PCE) of Femtosecond Small Incision Lenticule Extraction (SMILE) at depths of 100 um, 120um, 140um and 160um

Methods: This retrospective, comparative case series was designed to assess outcomes following SMILE procedures performed at a large surgical center by cornea specialists between May 1, 2020 and September 30, 2021. Four cap depth settings were compared: 100 um, 120um, 140um and 160um. Preoperative corneal biomechanical properties, posterior corneal elevation (PCE), total high-order aberrations (THOA), and endothelial cell density (ECD) by Scheimpflug Tomography (Pentacam AXL) , Dynamic Scheimpflug analyzer (Corvis ST) and specular microscopy (Konan SP 9000-LC) respectively, were measured preoperatively and on days 1, 7, 30 and 90 postoperative.
PCE changes by Pentacam were calculated at the corneal apex. Three parameters including deformation amplitude (DA), first applanation time (A1T), and second applanation time (A2T) were chosen for analysis, and then the ECD was automatically calculated by the computer software.

Results: A total of 140 patients (280 eyes) met the inclusion criteria: 70 eyes in 100nm cap depth SMILE group, 700 eyes in 120nm cap depth SMILE group, 70 eyes in 140nm cap depth SMILE group and 700 eyes in 160nm cap depth SMILE group.
Neither deformation amplitude (DA) nor the first applanation time (A1T) were significantly different between the groups. The second applanation time (A2T) was similar between the groups on days 1, 7, 30 with the exception of 90 days after surgery (22.52±0.18 ms in the 160-cap group versus 22.02 ±0.23 ms in the 140-cap group versus 21.84 ±0.24 ms in the 120-cap group versus 21.34 ±0.34 ms in the 100-cap group, p = 0.004). DA curve depth(μm) was steeper in the 100um depth cap, and the curve will be reduced as the SMILE has a deeper cap. AT2 will be significantly shorter in the 100um depth cap SMILE than in the 160um depth cap. No statistically significant differences were found between the different depth groups regarding THOA, ECD, CV and HEX.

Conclusions: A deeper cap while performing SMILE (140-160um) has less biomechanical effect in the cornea than SMILE with a cap created at 100-120 um.

ABSTRACT BODY:

Purpose: Imaging of the retinal pigment epithelium (RPE) monolayer in various retinal diseases poses a challenge considering the limited lateral resolution of commercially available devices and high reflectivity of the overlying photoreceptor layer in adaptive optics (AO) based imaging systems. We performed a prospective observational study to image the RPE using transscleral optical imaging (TOI) (Cellularis®, prototype), in patients with a clinical diagnosis of central serous chorioretinopathy (CSCR).

Methods: Twelve patients (mean age 43.3±4 years; 3 females, 9 males) with a clinical diagnosis of CSCR, in one or both eyes, underwent a comprehensive eye exam which included best corrected visual acuity, refractive error spherical equivalent and axial length. Demographic data included age and gender of the patient. A trained operator captured six 5.04° x 5.04° high resolution RPE images at different locations of each eye. All patients also underwent clinical imaging with color and autofluorescence fundus imaging as well as optical coherence tomography (OCT).

Results: TOI was successfully performed on 21 eyes with CSCR and one normal contralateral eye. Resolved CSCR eyes (N=15)showed an altered pattern of RPE mosaic in regions with RPE changes. Eyes with active CSCR (N=6) showed poor resolution of TOI imaging in regions with retinal detachment. TOI images revealed hyperreflective dots corresponding to areas of RPE hyperplasia or RPE detachments with hyperreflective content, and dark dots in some areas. Interestingly altered foveal RPE patterns were seen in some cases, even when the retinal morphology was normal on OCT.

Conclusions: TOI circumvents the drawbacks of conventional transpupillary AO imaging to perform cellular level imaging of RPE in CSCR. Various qualitative features such as altered mosaic pattern and hyperreflective dots help define sequelae at the level of RPE and inner choroid. Further understanding of the various qualitative signs on TOI and their correlation with multimodal imaging in CSCR is needed to explore the role of TOI in diagnosis, prognostication and treatment of various retinal conditions such as CSCR.

ABSTRACT BODY:

Purpose: Describe and analyze the effectiveness of triple palpebral therapy in signs and symptoms of evaporative dry eye using dynamic-keratograph parameters.

Methods: Retrospective study of patients with evaporative dry eye disease referred to palpebral therapy sessions from January 2019 to November 2021. Such therapy consisted of 3 sessions once a week during which patients underwent debridement- scaling of the lid margin, followed by moist-heat therapy with Blephasteam® for 10 minutes and meibomian gland manual expression (“Triple therapy”). Ocular Surface Disease Index (OSDI) questionnaire, noninvasive tear break-up time (NITBUT), recorded as the time to first rupture (NITBUTf) and the average time for rupture (NITBUTav), ocular redness, tear meniscus height (TMH) and meibography score were measured before and after the therapy using the OCULUS Keratograph® 5M. Paired t-test and chi-square analysis were used, and the level of statistical significance was taken as $p<0.05$.

Results: A total of 280 eyes (140 patients) were included, 71% were female. The mean age was 52.32±17.79 years. Meibomian gland abnormalities (grade 2-3) were found in 59.64% of cases, being the lower eyelid the most affected (71.43%). Pre-treatment TMH (millimeters), NITBUTf (seconds), NITBUTav (seconds), ocular redness and OSDI score were 0.22±0.16, 4.48±2.61, 7.03±3.51, 1.56±0.59 and 33.38±24.69, respectively. Post-treatment statistically significant improvement was found in TMH, NITBUTf, NITBUTav, ocular redness, and OSDI score with 0.34±0.20, 8.32±4.51, 11.08±4.77, 1.07±0.47, and 13.60±14.66, respectively ($p<.001$). Meibography scores had a non-significant statistical change ($p=.35$). Conjunctival chalasis was only found in 3.93% of cases. Ocular surface diseases other than primary evaporative dry eye disease were present in 10.7% of the eyes. No adverse effects were observed.

Conclusions: Triple therapy showed a significant improvement in evaporative dry eye signs and symptoms after the three-week sessions and appears to be an effective option for these patients. Studies to evaluate the long-term effect of the treatment may be necessary.

TITLE: Retinal Displacement On Fundus Autofluorescence Imaging: Only The Tip Of the Iceberg

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Bansal, R.H. Muni, St Michael's Hospital, Toronto, Ontario, CANADA|E. Roditi, K. Brosh, Shaare Zedek Medical Center, Jerusalem, Jerusalem, ISRAEL|

Commercial Relationships Disclosure: Aditya Bansal: Commercial Relationship: Code N (No Commercial Relationship) | Eudardo Roditi: Commercial Relationship: Code N (No Commercial Relationship) | Koby Brosh: Commercial Relationship: Code N (No Commercial Relationship) | Rajeev Muni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal displacement leads to worse functional outcomes following rhegmatogenous retinal detachment (RRD) repair. Although fundus autofluorescence (FAF) imaging can detect retinal displacement, there is a concern regarding its sensitivity & specificity. This study compares the accuracy with which FAF detects the presence and extent of retinal displacement.

Methods: A retrospective study of all patients with infrared (IR) images available before the occurrence of RRD and after RRD repair. At least 4 corresponding RPE and choroidal landmarks were marked on pre-RRD & post-RRD IR images extracted from the Heidelberg optical coherence tomography (OCT) software. Overlay of IR images based on the marked landmarks utilized a computer code in Python to compute the homography and then align the two images. The same procedure was carried out in the contralateral normal eyes to validate the technique. Two masked graders analyzed both the post-operative FAF and the IR overlay images to detect the presence and extent of retinal displacement.

Results: 14 eyes had both a pre-RRD & post-RRD repair OCT and a post-RRD FAF. In 8 patients, the contralateral eye had no other pathology or history of RRD. Homography was able to perfectly align the contralateral eye IR images in 100% (8/8) of cases (Fig 1). Retinal displacement was detected in 64.3% (9/14) of FAF images and in 92.8% (13/14) of IR overlay images respectively. The extent of retinal displacement was far greater as observed on the IR overlay images with a mean number of displaced vessels of 1.1 ± 0.88 in the FAF group and 2.9 ± 1.05 in the IR overlay group ($p=0.00004$). Qualitatively, the IR overlay method was superior at demonstrating both the presence and extent of retinal displacement compared to FAF (Fig 2). The IR overlay showed more extensive displacement in 92.8% (13/14) of cases.

Conclusions: FAF does not demonstrate the full extent of retinal displacement that is present and reveals only the “tip of the iceberg”. When available, overlay of pre-RRD & post-RRD repair IR images generated by OCT provides a better assessment of retinal displacement.

TITLE: Evaluation of foveal avascular zone associated with foveal pit restoration after idiopathic epiretinal membrane surgery

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Ryoo, B. Bae, Y. Choi, Ophthalmology, Veterans Health Service Medical Center, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Na-Kyung Ryoo: Commercial Relationship: Code N (No Commercial Relationship) | Byung-jin Bae: Commercial Relationship: Code N (No Commercial Relationship) | Young-Jae Choi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the relationship between ophthalmic parameters—including OCT and OCTA findings—and foveal pit restoration in eyes that had undergone vitrectomy for idiopathic epiretinal membrane (iERM) removal.

Methods: This study retrospectively analyzed data of patients who underwent 25-gauge pars planar vitrectomy (PPV) for the removal of ERM. Only eyes with iERM above stage 2 with a follow-up over 6 months were included. Baseline data and changes in ophthalmic parameters and their values were analyzed from 3 months before surgery to 12 months after the ERM surgery. Additionally, we stratified iERM patients into two groups (foveal pit restoration and no restoration group). Longitudinal comparison analyses between the two groups were done with the pre-and postoperative best-corrected visual acuity (BCVA), central foveal thickness (CFT), and superficial foveal avascular zone (FAZ) areas measurements using swept-source optical coherence tomography (SS-OCT) and optical coherence tomography angiography (OCTA).

Results: Overall, 43 patients with a mean age of 75± 5 years were enrolled in this study. After surgery, BCVA, FAZ, and CFT showed statistically significant improvements over time (all p-value <0.002). Thirty-one patients were designated into the foveal pit restoration (R) group and 12 patients into the no restoration (NR) group. Differences in BCVA and FAZ areas in both groups existed for up to 6 months. However, BCVA improved (R group: 0.12 ± 0.11 vs. NR group: 0.12 ± 0.07) and FAZ expanded (R: 0.20 ± 0.05 vs. NR: 0.18 ± 0.04) in both groups showing no statistical difference 12 months post-surgery. The CFT continuously decreased in both groups after removal of ERM, but the restoration group was thinner at every point compared to the no restoration group (all p-values < 0.05)

Conclusions: The removal of epiretinal membrane in PPV significantly improves BCVA, decreases the CFT and expands the superficial FAZ. Foveal pit restoration improves BCVA, CFT and FAZ area possibly at a faster rate in the early months but long-term improvements could be achieved regardless of the status of foveal pit restoration.

ABSTRACT BODY:

Purpose: Considering the devastating visual consequences of uveitis in the pediatric population, it is important to understand the social determinates of health (SDOH) that contribute to the visual outcomes these patients. We performed a retrospective observational study and cross-sectional survey to evaluate the relationship between SDOH and the visual outcomes of pediatric patients diagnosed with uveitis.

Methods: We conducted a survey and interview of 31 pediatric patients diagnosed with uveitis. We collected quantitative data to determine the social needs of patients and qualitative data about specific barriers or difficulties to see a uveitis specialist at the Emory Eye Center. We collected demographic and clinical information from the electronic medical record of these patients. Patients under the age of 18 with a diagnosis of uveitis were included in this study. The primary outcome of interest was final visual acuity. We utilized MAXQDA 2020 to analyze the qualitative data we collected in the survey.

Results: Of the 31 patients/parents surveyed, regarding barriers when seeking care, 35% stated they experienced no difficulty seeing a uveitis specialist, 26% mentioned a long driving distance, 19% mentioned difficulty with scheduling an appointment, 6% mentioned difficulty with payment/insurance issues, 6% had difficulties related to the uncertainty of the illness before their child was diagnosed, 3% had difficulty with referrals, and 3% experienced difficulty with taking time off work. The mean time from symptom onset to seeking care was 30.58 days and the median was 3 days. 39% of patient's first visited a pediatrician, 26% first went to an ophthalmologist, 16% went to an optometrist, 13% went to an urgent care, and 6% went to an ER. The average time of symptom onset to the first visit with a uveitis specialist was 356.23 days with a median of 94 days. On average the patients saw 2.1 other providers before being referred to Emory with a median 2. 52% (16/31) of the patients surveyed lived with both parents, 45% live with their mother, and 3% live with their father. Regarding final visual acuity, 48% of patients had vision >20/50, 32% were 20/50-20/200, and 19% were >20/200.

Conclusions: The main barriers to see a uveitis specialist were related to appointment scheduling issues, travel distance/time, and the difficulty of waiting for long periods of time in a waiting room with a child.

ABSTRACT BODY:

Purpose: Drusen burden is a key indicator of age-related macular degeneration (AMD) severity. Real time manual measurement of drusen volume (DV) by clinicians is not practical and automated estimates with inbuilt software save time, but are not readily available. Existing work on DV has shown variation between OCT devices and with automated vs. manually adjusted segmentation. We further examined this variation.

Methods: Retrospective, cross-sectional study of intermediate AMD eyes imaged with macula centered 97 line enhanced depth imaging OCT (Spectralis, Heidelberg). Volume scans were processed for automated segmentation of the RPE and BM to generate the drusen volume. To manually adjust segmentation, RPE and BM were fit to demarcation in each B-scan prior to calculating DV. The average retinal thickness (RT) and DV, and highest retinal pigment epithelium/Bruch's Membrane thickness (RPEBMt) were measured in all 9 ETDRS grid sectors. Multi-level linear regression models, accounting for participant and eye-in-participant levels, were used to associate the log RT and log DV measurements with the processing method (automated vs. manual), RPEBMt(continuous measure), and their interaction.

Results: We included 10 eyes of 5 participants. Over entire ETDRS grid, the mean difference between manual and automated processing for RT and DV was 7.9±21.1 μm and 0.015±0.04 mm^3, respectively. Larger differences between manual and automated methods were observed for inner grid segments (GS) and the center than the outer GS for both RT (Inner: 12.3±26.6 μm; Outer: 2.5±8.4 μm) and DV (Inner: 0.017±0.037 mm^3; Outer: 0.012±0.044 mm^3). The mean±SD of RPEBMt parameter was 85.3±51.9μ. Significant interaction seen between RPEBMt and processing method for both RT (β=0.006, $p<0.001$) and DV (β=0.007, $p<0.001$), meaning the variation between manual and automated processing became larger as the RPEBMt increased.

Conclusions: Presence of large drusen affected the automated segmentation resulting in larger deviations, as measured by significant association between RPEBMt and DV and RT, compared to the manual segmentation. In eyes with large drusen, the current automated segmentation does not reliably measure these parameters, and there is a need for manual review to mitigate the effects of segmentation compromise.

ABSTRACT BODY:

Purpose: Large choroidal melanomas are still a common presentation. Treatment with plaque brachytherapy (PB) has historically demonstrated poor outcomes including increased risk of local failure and severe vision loss. The purpose of our study is to report on the outcomes for large choroidal melanomas treated with PB and prophylactic adjuvant bevacizumab.

Methods: A prospective consecutive case series of patients with large choroidal melanomas treated with I-125 (^{125}I) PB. Outcomes included local tumor failure, survival, secondary enucleation and visual acuity.

Results: In total, 87 patients with a large choroidal melanoma were identified. 54 (62.1%) patients were treated with PB and 33 (37.9%) were treated with primary enucleation. A large choroidal melanoma was defined as having a maximum tumor diameter of >16.0 mm or an apex height >10.0 mm regardless of diameter. Of the 33 primary enucleation patients, the mean tumor apex height was 11.1 ± 2.8 mm (3.5 mm – 14.9 mm) and the mean maximal basal diameter was 16.6 ± 3.2 mm (10.5 mm – 23.0 mm). Of the 54 PB patients, the mean tumor apex height was 9.3 ± 3.0 mm (2.0 mm – 14.8 mm) and the mean maximal basal diameter was 16.7 ± 2.2 mm (9.2 mm – 20.5 mm). Of the 54 PB patients, the overall survival rate was 35/54 (64.8%) with a mean follow-up time was 3.6 ± 95% confidence interval of 2.5 years. The local failure rate was 0/54 (0.0%) and the secondary enucleation rate was 3/54 (5.6%). Visual acuity was better than 20/200 in 40% of the patients at a mean follow-up time of 3.6 ± 2.5 years.

Conclusions: Plaque brachytherapy provides excellent local tumor control, an eye preservation rate of 94.4%, and a 65% overall survival rate with a mean follow-up of 3.5 years. Visual acuity was better than 20/200 in 40% of the patients.

ABSTRACT BODY:

Purpose: Cardiovascular disease is the number one cause of death in the world, and frequently goes unnoticed until the occurrence of serious events such as heart attack or stroke. Therefore, early detection of occult cardiovascular disease, prior to catastrophic illness, is critical. We sought to determine whether retinal ischemic perivascular lesions (RIPLs), which are anatomical biomarkers of subclinical microvascular ischemia in the retina, can be used to detect occult cardiovascular disease.

Methods: We identified individuals with no significant retinal pathologies and who had RIPLs detected on spectral domain optical coherence tomography (SD-OCT) scans during routine retinal examination in our clinic. We excluded individuals with pre-existing cardiovascular disease, diabetes, and those who did not have a follow-up medical visit. Additionally, we excluded patients with any retinal pathology including diabetic retinopathy. We reviewed the medical chart and present the medical outcome of subjects who had subsequent cardiovascular workup prompted by RIPLs detection.

Results: We identified thirty-six patients, with incidental RIPL identification on SD-OCT at the time of examination. A total of 25 patients were excluded. Of the 11 subjects that were included, 5 were males and 6 were females. Ages ranged from 44 to 80 years. The eleven subjects with no prior history of cardiovascular disease, other than essential HTN, followed up with their primary care physician or cardiologist for age-appropriate cardiovascular work-up. Of these, newly diagnosed cardiovascular disease was identified in 8 individuals (72.7%), including three-vessel CAD, significant carotid artery stenosis, soft carotid plaque, reduced cardiac ejection fraction, patent foramen ovale, cerebral infarction, subclavian steal syndrome and undiagnosed or uncontrolled HTN. Two patients subsequently underwent invasive procedures including coronary artery bypass grafting (CABG) and carotid artery stent placement. Three patients were started on new medical therapy for their conditions, and two were advised to undergo periodic follow up.

Conclusions: Our findings indicate that presence of RIPLs, which are anatomical markers of prior retinal ischemic infarcts, may indicate the need for cardiovascular referral which in some cases can lead to important interventional management.

ABSTRACT BODY:

Purpose: To determine the effectiveness of telehealth (TH) services delivered by a health extender in promoting patients with diabetic retinopathy (DR) who are overdue for care to schedule and/or return for in-clinic eye examinations.

Methods: Established patients with DR who had not been seen within the last year were identified by a retrospective review of the EMR using a reporting tool. Patients who had not returned for follow-up care were contacted by phone by a TH extender. Each patient was offered screening for acute eye problems by means of a symptom-based screening script. Those patients who raised concerns about vision-related issues were offered transfer to a physician for triage. Finally, patients were offered assistance in scheduling an in-person clinic visit.

Results: 159 patients with DR potentially overdue for care were contacted by phone. 43% of calls reached patients; 52% of calls went to patient voicemail (VM) where instructions were left for appointment-booking; 5.0% of patients were unreachable, and 2.9% of patients contacted were identified to be deceased. Of the 67 patients reached by phone, 39% reported that they had transferred/declined further care. Of the remaining 41 patients, 77% agreed to take the symptom survey, and out of those 91% went on to book a booked an appointment, including one patient who required transfer to physician triage and was brought into the clinic the next day for management of proliferative retinopathy. By contrast, the 3 patients who chose not to book an appointment after the symptom survey all reported no symptoms. A further 3 patients scheduled despite declining the symptom survey. Finally, 5 patients (12%) requested to be called back later and 3 patients (7.3%) to call back themselves. In total, 27% of patients contacted through the program ultimately booked an appointment, including 12% who were left a VM and 1 patient who was called back by a scheduler. This rate of appointment booking was more than twice that of a larger cohort of patients who were overdue for care but not engaged by the program (27% vs. 11%, X^2=9.561; P=0.002).

Conclusions: Nearly one-third of patients with DR identified as being overdue for eye care and contacted by a TH extender made follow-up appointments. This study adds to the growing body of research that TH, even when delivered by a non-provider, can help improve the rate at which patients with DR access eye care.

ABSTRACT BODY:

Purpose: The reliability of a scientific measurement is usually estimated from variability across repeated measurements, with standard error (SE) estimating variability in the mean. However, conventional visual field tests are labor intensive, so it is not practical to collect repeated measurements. New at-home tests with redesigned psychophysical procedures have recently made it practical for patients to undertake a “bundle” of 10 tests at home within a period of 5-14 days (Deiner, Damato, & Ou, 2020. Ophthalmology 127:1258) for which a mean and SE can be computed.

Methods: Patients from the UCSF Glaucoma Clinic were provided a mobile VR headset (Oculus Go, Facebook Inc) running Vivid Vision Perimetry (VVP) software (Vivid Vision Inc, San Francisco, CA). Patients received virtual training while at home and were then asked to perform VVP 10 times within a two-week period at intervals of approximately four months. Tested field locations were arrayed in the Humphrey 24-2 layout. Each location was tested four times per test with a fixed-contrast stimulus chosen to be close to threshold at locations having a sensitivity of 15 dB in conventional HVFA. Percent seen was the dependent variable.

Results: Between April 2020 and October 2021, 24 patients took 1472 tests in 142 bundles, each containing 5 to 15 tests apiece (mean 10.3, SD 1.9). Percent seen varied from 0% to 100% depending on sensitivity at the location, corresponding to a dynamic range of approximately 5 to 25 dB (HVFA). Mean sensitivity (MS) for each of the 1472 tests was percent seen across 52 locations, not including near the blind spot. Bundle SE was 1.2% on average (std dev 0.9%), corresponding to a test-retest variability of 0.24 dB in HVFA units for the bundle, which compares favorably with the test-retest variability of HVFA in glaucomatous eyes, usually estimated between 0.5 and 1.0 dB. 21 of the bundles contained an outlier (interquartile test); it was generally worse, not better, than the bundle mean. Data review suggested that a change in MS of > 2 SE be used to detect changes in vision.

Conclusions: The SE for a bundle of visual field tests provides a clinically practical objective measure of test reliability. It quantifies the statistical difference between test epochs when monitoring progressive field loss in diseases like glaucoma.

ABSTRACT BODY:

Purpose: The American Academy of Ophthalmology (AAO) developed Preferred Practice Pattern (PPP) guidelines to standardize the frequency of comprehensive eye exams (CEEs) for specific patient groups. These guidelines may benefit Primary Care Provider (PCPs), who often serve as patients' only touchpoints with the healthcare system. However, PCPs' familiarity with these guidelines is unclear. We surveyed PCPs' familiarity and compliance with CEE guidelines, and whether these patterns varied according to practitioner training level, length of experience, or state.

Methods: We surveyed PCPs, primary care residents, physician assistants (PA), and nurse practitioners (NP) affiliated with two academic medical centers in Boston, MA, and Oklahoma City, OK, as well as a sample of private practice PCPs in Oklahoma. Respondents were given five clinical vignettes and asked to indicate when the patient should be referred for a CEE. Additional questions assessed participants' familiarity with PPPs for CEEs, attitudes toward CEE guidelines, and perceived barriers to utilizing such guidelines. Groups were compared using chi-squared or Fisher's exact tests.

Results: The response rate was 216/336 (64.3%). Around half of PCPs (48.1%) reported "usually" counseling patients regarding CEEs; 15.4% reported "always" doing so, while 36.5% reported "seldom" or "never". Few PCPs (10.6%) were able to accurately describe specific guidelines, whereas two-thirds (63.9%) were unaware of their existence. OK-based PCPs reported greater familiarity with PPP guidelines than MA PCPs ($p=0.02$). Alignment with disease-specific PPPs varied considerably; a strong majority of PCPs (90.7%) correctly referred a type II diabetic at their time of diagnosis, but a similar majority (77.8%) inappropriately referred a newly-diagnosed type I diabetic. 13.4% of PCPs would not refer a young patient with family history of glaucoma until they developed visual symptoms. Compared to other providers, NPs/PAs were more likely to recommend unnecessary CEEs for low risk young adults ($p=0.04$), while residents counseled patients less frequently ($p<0.01$), were less likely to be aware of PPP guidelines ($p=0.03$), and less likely to properly recommend baseline exams.

Conclusions: PCPs' familiarity with CEE guidelines is suboptimal. Targeted efforts to improve PCP guideline awareness may be especially well suited for residents and mid-level practitioners.

TITLE: Targeting High Glucose-Induced Mitochondrial Fragmentation: Implications for diabetic retinopathy

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Sankaramoorthy, S. Roy, Boston University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Aravind Sankaramoorthy: Commercial Relationship: Code N (No Commercial Relationship) | Sayon Roy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy is characterized by loss of vascular endothelial cells as a result of apoptosis. During apoptosis mitochondria undergo fragmentation, which is sustained/orchestrated at least in part by the action of dynamin-related protein 1 (Drp1) protein, a regulator of mitochondrial fission. In this study, we determined whether downregulation of high glucose (HG)-induced increased mitochondrial fragmentation could be prevented by targeting Drp1 overexpression and thereby inhibiting apoptosis in rat retinal endothelial cells (RRECs).

Methods: RRECs were grown in normal (N; 5mM glucose) or HG (30mM glucose) media for 7 days; in parallel, RRECs were grown in HG medium and transfected with Drp1 siRNA, or exposed to Mdivi-1, a Drp1 inhibitor. To determine Drp1 levels in these cells, total protein was isolated and subjected to Western blot (WB) analysis. The extent of mitochondrial fragmentation was assessed using live cell confocal imaging after staining with MitoTracker Red and analysed for form factor (FF) and aspect ratio (AR). TUNEL assay was performed, to determine the effect of reducing mitochondrial fission on apoptosis.

Results: WB analysis showed significant Drp1 upregulation in cells grown in HG compared to those grown in N medium (143±17% of normal, $p=0.0004$); cells grown in HG medium transfected with Drp1 siRNA showed significant Drp1 downregulation (97±35% of HG, $p=0.003$). Live cell imaging using confocal microscopy revealed that cells grown in HG medium showed significant mitochondrial fragmentation (FF = 1.91, $p=0.001$; AR = 1.98, $p=0.001$). Interestingly, cells grown in HG medium and transfected with Drp1 siRNA or exposed to Mdivi-1 showed a significant decrease in mitochondrial fragmentation (FF = 3.68, AR = 2.46 $p=0.001$; FF = 3.63, AR = 2.57 $p=0.001$, respectively). In addition, cells grown in HG exhibited increased number of TUNEL positive cells (231±8% of normal $p<0.05$) compared to cells grown in N medium. Importantly, when cells grown in HG were transfected with Drp1 siRNA, this resulted in a significant decrease in the number of TUNEL positive cells (125±12% of HG $p<0.05$).

Conclusions: Findings from this study indicate that targeting HG-induced Drp1 overexpression may have beneficial effects in protecting against HG-induced mitochondrial fission and apoptotic cell loss associated with the pathogenesis of diabetic retinopathy.

ABSTRACT BODY:

Purpose: Visual impairments in children with brain injury, such as from spontaneous arteriovenous malformation (AVM) rupture, are difficult to assess through conventional methods due to their co-occurrence with communicative and cognitive disabilities. As a consequence, impairments are often only determined through subjective evaluations of gaze-based reactions to different forms and movements. We recently developed a system to grade visual health based on eye movements and evidence from gaze-based tracking behaviors that can be used in communicative and non- communicative children alike. We use this approach here to assess visual impairment and recovery of function following AVM rupture.

Methods: Our approach, the "Visual Ladder" efficiently produces gaze-based metrics that grade a participant’s saccades, pursuits, visual field responsiveness, and spatial visual function from tracking responses to static and moving stimuli. We used the Visual Ladder to periodically assess five children aged 7-18 while hospitalized at a children’s rehabilitation hospital after being treated for an AVM rupture in the brain. Children in the study were verbal and had no known medical problems prior to injury. After reparative surgery and admission to a rehabilitation hospital, however, the children became non-communicative and had limited mobility. While at the hospital we measured the speed and directional biases of their eye movements, pathological nystagmus, visual field asymmetries, and contrast sensitivity deficits.

Results: Children were tested periodically until discharge and they all five showed improvement in their eye-movement-based metrics using the Visual Ladder, as well as their communication, cognitive, and physical abilities as assessed by hospital therapists as part of their routine standard of care. Fig. 1 depicts an example of one child's mean saccades and pursuits 1 month post treatment for AVM rupture (A and B respectively) and 8 months post recovery (C and D). The distributions at 8 months are far from normative.

Conclusions: Our findings indicate that eye-tracking-based tasks enable the measurement of visual metrics in young and impaired individuals. Quantitative assessments in these clinical populations would aid in a much-needed objective diagnostic tool and therapy tool for non-communicative and/or brain injured populations.

ABSTRACT BODY:

Purpose: Sunlight wavelengths of different energy are key environmental factors in the development of skin photo-damage, photoaging, and carcinogenesis. High-energy wavelengths of ultraviolet radiation zone (UVR) are known etiologic agents in the pathogenesis of basal cell carcinoma (BCC) and contributes to photodamage in dermal layers of the skin. Clinical data from our laboratory shows that lower eyelid BCC tends to develop under moderate-to-severe elastosis. In this study, we evaluated the acute effect of different artificial sunlight exposures in keratinocytes and fibroblasts, and assessed the consequences of partial-to-full UVR blockage.

Methods: Four human cell types were used: two normal primary epidermal keratinocytes, and two normal fibroblasts. Cells were exposed to one sun by a Tri-Sol solar simulator (300-1800 nm). Exposure conditions included full sun (FS), exposure to long path filters that partially or completely blocked UVR, and a non-sun light exposure block (B). Following solar stimulation, we evaluated the cells' metabolic capacity and total reactive oxygen species (ROS) production in the presence or absence of antioxidant N-acetyl Cysteine (NAC).

Results: The primary keratinocytes' metabolic capacity was unaffected when exposed to FS, similarly as B. The FS significantly decreased the metabolic capacity of the fibroblasts. When wavelengths below 360 nm were blocked, both cell types experienced a significant decrease in their metabolic capacity. Co-incubation with NAC during exposure prevented a decrease in metabolic capacity of both keratinocytes and fibroblasts, particularly with filtered UVR. In both cells, FS exposure induced a significant increase in total ROS when compared to B exposure. In fibroblasts, unlike keratinocytes, blockage of UVR resulted in higher levels of ROS when compared to FS exposure.

Conclusions: Exposure to FS induces different acute effects in keratinocytes and fibroblasts. Filtered UVR causes a significant decrease in the metabolic capacity in both cell types, which is prevented by NAC. ROS levels increase when cells are exposed to FS; fibroblasts, contrary to keratinocytes, show higher ROS levels when UVR is blocked. Our data suggest that the decrease in cellular metabolic activity caused by complete UVR blockage could be due to increased ROS levels as it was rescued by NAC.

TITLE: Does sclera deform under electric field?

SESSION TITLE: Structure-Function Relationship

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Hatami-Marbini, J. Arash Mehr, Mechanical Engineering, University of Illinois at Chicago College of Engineering, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Hamed Hatami-Marbini: Commercial Relationship: Code N (No Commercial Relationship) | Jafar Arash Mehr: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To test the hypothesis that the sclera is an electroactive hydrogel and determine its electromechanical properties.

Methods: Scleral strips were dissected from the area close to the optic nerve head in the superior-inferior direction from porcine eyeballs. After measuring the thickness of the strips using a pachymeter, they were mounted at the center of a custom-designed container between two carbon electrodes. The scleral samples were fixed from one side and their other end was free to move. After filling chamber with NaCl solution, the two carbon electrodes were connected to a DC current power supply and the strips were subjected to 5, 10, and 15 volts for 60 seconds. The deformation of strips was recorded by a digital microscope camera as a function of time during the experiments.

Results: The average thickness of porcine posterior sclera samples was found to be 1.3 mm at the beginning of the experiments. No difference in the thickness of the samples was observed after they were removed from the custom-made container. Upon applying the electric voltage, the strips started to bend towards the cathode, Figure 1. The amount of bending of the scleral strips gradually increased with time and its magnitude was a function of the applied voltage. The maximum bending angle of scleral strips was 2.6±0.5, 11.4±1.0, and 22.4±1.6 at 5, 10, and 15 V, respectively.

Conclusions: It was found that the sclera is an electroactive tissue that mechanically deforms when subjected to DC electric voltage. The amount of deformation depends on the strength of the electric field and the duration of the application of the electric voltage. These findings are important for both biomechanical and biochemical characterizations of the sclera and have important implications for the future efforts to characterize the electromechanical properties of ocular tissues.

ABSTRACT BODY:

Purpose: Cannabis is a widely consumed hallucinogenic substance and has previously been linked to central neurotransmission abnormalities. Its chronic use is a public health concern due to reported risk of neurotoxicity which could affect visual processing and neurological development. The purpose of this study is to establish the impact of chronic and acute cannabis use on various levels of visual processing in a population of regular cannabis users.

Methods: Six regular cannabis users, and 7 control non-users underwent complete ophthalmological examination including electrophysiological testing: Visual Evoked Potential (VEP) and electroretinogram (ERG). The testing was repeated twice in regular users: 24 hours [chronic use] and 2.5 hours [acute] following cannabis consumption.

Results: There was no difference between groups in terms of age ($p=0.81$), sex ($p = 0.99$), co-occurrent alcohol and smoking ($p=0.78$ and 0.36). Ophthalmological and electrophysiological testing were within normal limits for both cohorts. No significant difference in the cohorts was found when comparing full field ERG, pattern ERG, and VEP results. A difference was noted in a-wave amplitudes, (Figure 1), which were lowest for acute users and highest for controls at different light intensities, but this failed to meet clinical significance.

Conclusions: Current data suggest that there is no significant impact on visual processing despite chronic or acute use of cannabis. However, there is a possible trend toward diminished photoreceptor function in cannabis use that warrants further higher powered studies. Data collection is ongoing.

ABSTRACT BODY:

Purpose: To determine the changes in the exogenous RNA transcriptome of the aqueous humor in patients with diabetes mellitus without diabetic retinopathy or with proliferative diabetic retinopathy, and to screen for genes linked with diabetic retinopathy progression.

Methods: Aqueous humor (100 ul) was collected in case-control cohorts of 15 healthy controls, 14 diabetic patients without diabetic retinopathy, 12 patients with nonproliferative diabetic retinopathy, and 14 patients with proliferative diabetic retinopathy. We were able to obtain total RNA sequencing results from 14 healthy controls, 5 patients with diabetes without diabetic retinopathy, and 7 patients with proliferative diabetic retinopathy. Genes differentially expressed between patients with or without diabetes as well as diabetic patients with or without diabetic retinopathy were identified using DESeq2.

Results: Three hundred thirty-eight genes were found to be differentially abundant in the aqueous humor (False Discovery Rate < 0.1) of diabetic patients without retinopathy vs controls, and 44 genes in diabetic patients without diabetic retinopathy vs with diabetic retinopathy. CACNB2 and CACNG8, two voltage-gated calcium channel proteins highly expressed in retinal cells and linked to VEGF signaling, and SLC22A11, a glucose transporter, were the top three up-regulated gene in the proliferative diabetic retinopathy cohort.

Conclusions: We were able to discern differences in the RNA composition of the aqueous humor of patients with diabetes with or without diabetic retinopathy compared to healthy controls. Our top candidate, CACNB2, has been previously associated with VEGF regulation in GWAS studies and confirms the role of VEGF signaling in diabetic retinopathy. Aqueous humor is a relatively easy to obtain biofluid, and our results reveals it contains a diverse transcriptome which has potential for disease progression monitoring and discovery of disease-associated gene networks.

ABSTRACT BODY:

Purpose: There is a significant gender disparity in ophthalmology, with 22.7% of the workforce consisting of women. Differences in research funding and support may contribute to the disparities, so we sought to identify factors where these disparities in research support and productivity currently exist within the field of neuro-ophthalmology. To our knowledge, this is the first study to investigate sex differences in scholarly productivity, academic rank, and NIH funding among neuro-ophthalmologists.

Methods: This study was a cross-sectional study of academic neuro-ophthalmologists of all 113 US ophthalmology programs. Using institutional websites, data on sex, residency graduation year, and academic rank were collected. Scopus database was used to obtain each faculty's h-index, and m-quotient was calculated based on each faculty members h-index/career duration. The NIH Research Portfolio Online Reporting Tool database was queried for data on NIH funding. Chi-square testing was used to analyze categorical values and Wilcoxon Rank Sum testing was used for continuous variables.

Results: A total of 210 academic neuro-ophthalmologists were identified, of whom 64 (30.5%) were female and 146 (69.5%) were male. A significantly greater proportion of females vs. males were assistant professors [37 (57.8%) vs. 48 (32.9%); p=0.008]. Although not statistically significant, a smaller proportion of females were full professors [14 (21.9%) vs. 62 (69.5%); p=0.051]. No significance difference was found among associate professors [female: 13 (20.3%) vs. male: 35 (24.0%); p=1.000]. One female neuro-ophthalmologist held the departmental chair position, while nine positions were held by male counterparts [1 (1.6%) vs. 9 (6.5%); p = 1.000]. Females had similar median h-indices compared to their male counterparts (6.0 vs. 10.5; p=0.124) as well as similar median m-quotients (0.5 vs 0.6; p=1.000). Females had a shorter median career duration based on their residency graduation year compared to males (15.0 vs 28.0 years; p <0.001). Among the 43 neuro-ophthalmologists who received NIH funding for research, of whom 13 (30.2%) were female and 30 (69.8%) were male, females had a median grant funding of $1.1M compared to $574K for males (p=1.000).

Conclusions: Females had similar h-indices compared to males. There was no difference in m-quotients between sexes, which controlled for the specialists' career durations.

ABSTRACT BODY:

Purpose: Loss of barrier integrity due to endothelial cell damage or dysfunction is common in retinal microvascular diseases such as diabetic retinopathy. We reported previously, the expression of the beta-hydroxybutyrate (BHB) receptor HCAR2/GPR109A in retina where it localizes robustly to the basolateral membrane of the retinal pigment epithelium (RPE) and regulates outer retinal barrier integrity. Our recent work confirms receptor expression also in retinal endothelial cells. However, its functional relevance in these cells is not well understood. Here, we examined relevance of receptor expression to endothelial cell dependent (inner)-blood retinal barrier integrity.

Methods: DasiRNA technology was used to modulate HCAR2/GPR109A expression in primary human retinal endothelial cells (HRECs). Scrambled control and Hcar2/Gpr109a-knockdown HRECs were grown on transwell filters for 4-6 weeks. qPCR was used to monitor HCAR2/GPR109A expression and electrical cell impedance sensing (ECIS) technology to evaluate barrier function. To investigate the relevance of HCAR2/GPR109A expression to barrier function in vivo, retinal inflammation was induced in wildtype and HCAR2/knockout mice using LPS (4 mg/kg). Single cell suspensions prepared from retinal homogenates obtained mice injected intraperitoneally LPS or PBS (control) +/- HCAR2/GPR109A agonist BHB were assessed by flow cytometry to monitor immune cell infiltration.

Results: Absence (KO) or reduction (siRNA) of HCAR2/GPR109A expression impaired barrier function (ECIS) significantly contributing to the increased infiltration of pro-inflammatory immune cells in retina as indicated by flow studies. BHB treatment preserved retinal barrier integrity and prevented increased immune cell infiltration in retina even in the presence of a pro-inflammatory stimulus (LPS), an effect that was receptor (HCAR2/GPR109A)-dependent.

Conclusions: Collectively, these data establish a role for HCAR2/GPR109A in regulating retinal endothelial cell barrier function in normal and inflammatory conditions. Thus, highlighting the therapeutic potential that targeting the receptor holds with respect to prevention and treatment of degenerative retinal diseases like diabetic retinopathy in which compromised barrier function is paramount.

TITLE: Response of Drusen Volume to Curcumin is Correlated with Risk Alleles for Age-Related Macular Degeneration

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Pfahler, I. Bielskus, P.A. Knepper, Ophthalmology and Visual Sciences, University of Illinois at Chicago College of Medicine, Chicago, Illinois, UNITED STATES|N.J. Volpe, S. Aman, Z. Zaparackas, P.A. Knepper, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Nicholas Pfahler: Commercial Relationship: Code N (No Commercial Relationship) | Indre Bielskus: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Volpe: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Aman: Commercial Relationship: Code N (No Commercial Relationship) | Zibute Zaparackas: Commercial Relationship: Code N (No Commercial Relationship) | Paul Knepper: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a multifactorial disease with known genetic associations. The ability to forecast morphological changes and treatment response based on genetic and clinical risk factors would be a valuable tool for clinicians. This study evaluated the association between the number of risk alleles for AMD and drusen volume change over two years in a group of AMD subjects taking curcumin.

Methods: Participants were recruited from the office of Zaparackas and Knepper, Ltd. in Chicago, IL after IRB approval and informed consent. All participants (n=17) had drusen ≥63 μm without geographic atrophy or choroidal neovascularization. Participants took oral curcumin (2.66 g/day) and were imaged using OCT for a period of two years. Drusen were categorized by width as 63-124 μm, 125-249 μm, and ≥250 μm. Genetic samples were analyzed by Arctic Medical Laboratories (Grand Rapids, MI). AMD risk alleles evaluated included C2, C3, CFB, CFH (rs412852, rs3766405, rs1048663), CFI, ABCA1, APOE, ARMS2, CETP, COL8A1, LIPC, and TIMP3. Drusen volume was measured in mm^3. Pearson's correlations were used to assess the associations between number of AMD risk alleles and change in drusen volume during the study.

Results: A lower number of overall risk alleles (r=0.65, p=0.009) and of complement system risk alleles (r=0.68, p=0.005) was correlated with a larger decrease in drusen volume after two years. Individually, a lower number of ARMS2 (r=0.55, p=0.04) and CFH rs3766405 (r=0.61, p=0.02) risk alleles was correlated with a larger decrease in volume. A high-risk genetic profile composed of the number of risk alleles for ARMS2, CFH rs412852, CFH rs3766405, C3, and CFI significantly predicted smaller changes in volume over time (r=0.75, p=0.001). The number of risk alleles overall, in complement system genes, and in ARMS2 and CFH were correlated with volume change in drusen 125-249 μm and ≥250 μm but not in drusen 63-124 μm.

Conclusions: The response of drusen to curcumin supplementation is associated with the genetic profile of the patient. A higher number of certain risk alleles is associated with a worse response to curcumin. This explains the variable responses of AMD patients to supplementation with other antioxidants such as AREDS.

TITLE: Sex and racial/ethnic diversity among ophthalmology fellowship applicants.

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Zafar, M. Ali, F. Woreta, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|M. Menard, Meharry Medical College, Nashville, Tennessee, UNITED STATES|B.K. Williams, University of Cincinnati, Cincinnati, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Sidra Zafar: Commercial Relationship: Code N (No Commercial Relationship) | Muhammad Ali: Commercial Relationship: Code N (No Commercial Relationship) | Maylander Menard: Commercial Relationship: Code N (No Commercial Relationship) | Basil Williams: Commercial Relationship: Code N (No Commercial Relationship) | Fasika Woreta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There remains a dearth of literature on sex and racial/ethnic diversity trends among ophthalmology fellowship applicants. Our study purpose was to investigate the proportion of female and under-represented minorities (URMs) among ophthalmology fellowship match applicants.

Methods: De-identifed San Francisco (SF) matching data for ophthalmology fellowship applicants in the U.S. for 2019 and 2010 was analyzed.

Results: Between 2019 and 2020, there were a total 698 ophthalmology fellowship applicants. Of these, 283 (40.5%) were males, 200 (28.7%) females and 215 (30.8%) did not disclose their gender. In terms of race/ethnicity, only 51 (7.7%) identified as URMs, and 213 (32.1%) did not disclose their race. There were significant differences in the mean number of distributions and mean number of interviews completed between URMs and non-URMs (<0.001). The proportion of matched male and female applicants among cornea, glaucoma, retina, and pediatric ophthalmology was: 34.9% vs 30.1%, 43.7% vs 29.1%, 47.2% vs 19.9% and 32.5% and 47%. Among males, the most popular subspecialties were: retina (41%), glaucoma (24.4%), cornea (20.5%) and pediatric ophthalmology (9.5%). Among females, the most popular subspecialities were: cornea (25%), retina (24.5%), glaucoma (23%) and pediatric ophthalmology (19.5%). There was no association between sex and race/ethnicity and match outcomes.

Conclusions: The percentage of URMs applying for fellowship in ophthalmology remains low, and the number of interviews they receive is significantly less than non-URMs. The percentage of females in all subspecialities of ophthalmology except pediatrics remains low. More efforts are needed to collect data on gender and race/ethnicity and improve representation in ophthalmology.

ABSTRACT BODY:

Purpose: Little is known regarding the role of primary cilia, in aged oligodendrocytes (OLGs), which tend to be dysfunctional in neurodegenerative diseases. To investigate if primary cilia in aged OLGs might be involved in the age-related degeneration of vision, we examined the length and frequency of OLG primary cilia in the optic nerves of young and aged C57BL/6 wild-type mice.

Methods: Cryosections of the optic nerve and optic chiasm were prepared from the eyes of 8 young and aged C57BL/6 mice (3 and 20 months). Samples were immunostained with anti-Arl13b, anti-Oligo2, and anti-MBP to visualize primary cilia and OLGs, and imaged by confocal microscopy. Images of the anterior and posterior optic nerve and optic chiasm were examined, and statistical analysis was performed using the One-way ANOVA and Student's t-test.

Results: The ciliation of Oligo2-positive OLGs in the anterior optic nerve was 8.6 ± 5.9% and 7.7 ± 4.1% in young and aged mice, respectively. The ciliation of Oligo2-positive OLGs in the optic chiasm was 5.4 ± 4.5% and 5.6 ± 3.8% in young and aged mice, respectively. There were no significant changes in ciliation between the young and aged groups. In 3-month-old mice, the mean ciliary length of Oligo-2-positive OLGs was similar in the anterior and posterior optic nerve (1.12 ± 0.80 um and 1.25 ± 1.06 um, respectively). In 20-month-old mice, the mean ciliary length was significantly greater in the anterior optic nerve than in the posterior optic nerve (1.73 ± 1.26 μm and 1.00 ± 0.38 μm, $P<0.05$, respectively).

Conclusions: We reported a novel regional difference in OLG primary cilia length in the optic nerves of aged mice, suggesting that primary cilia may play a role in OLGs and myelination disorders.

TITLE: The role of the RNA-binding protein Elavl1 in lens development

SESSION TITLE: Lens Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Coomson, S. Aryal, S.A. Lachke, Department of Biological Sciences, University of Delaware, Newark, Delaware, UNITED STATES|S.A. Lachke, Center for Bioinformatics and Computational Biology, University of Delaware, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure: Sarah Coomson: Commercial Relationship: Code N (No Commercial Relationship) | Sandeep Aryal: Commercial Relationship: Code N (No Commercial Relationship) | Salil Lachke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Analogous to DNA-binding proteins called transcription factors (TFs) that bind DNA and mediate transcriptional control, RNA-binding proteins (RBPs) bind RNA and control its post-transcriptional fate, such as splicing, transport, localization, stability and translation into protein. While there are more genes in the human genome that encode RBPs compared to DNA-binding proteins, the former class of proteins are grossly less studied compared to the latter, especially in the context of eye development. To address this knowledge-gap, efforts over the past decade have identified several RBPs (e.g. Caprin2, Celf1, Rbm24, Tdrd7, among others) that are required for proper lens development and whose deficiency causes lens defects and/or cataracts (Lachke (2022) PMID: 34906599). To further advance the role of RBPs in the lens, we used iSyTE to identify Elavl1 (ELAV (embryonic lethal, abnormal vision)-like 1; also called HuR (Hu antigen R) as a high-priority candidate and analyzed its relevance to lens development.

Methods: Elavl1 expression in mouse lens was analyzed by RT-PCR, Western Blotting and immunofluorescence staining (IF). Elavl1 lens-specific conditional knockout ($Elavl1^{cKO}$) mice were generated by crossing mice containing Elavl1 floxed alleles and the Pax6GFPCre mouse line. RNA-IP (RIP) using Elavl1 antibody was performed on wild-type post-natal day (P) 15 mouse lens lysates Elavl1.

Results: Using the systems-based tool for eye gene discovery, iSyTE, we predicted Elavl1 to be robustly expressed in the lens. RT-PCR, WB and IF independently validated Elavl1 expression in embryonic and postnatal lens. Further, Elavl1 protein was detected in both anterior epithelium of the lens and fiber cells. $Elavl1^{cKO}$ mice exhibit microphthalmia and/or lens defects and cataract that progress with age. Initial studies suggest that several lens markers are misexpressed in the $Elavl1^{cKO}$ lens. Further, RIP assays demonstrate that Elavl1 protein binds Pax6 and Prox1 mRNA in lens cells. These findings suggest that Elavl1 may be involved in post-transcriptionally controling these TFs in the lens.

Conclusions: These data demonstrate that Elavl1 is robustly expressed on both RNA and protein levels in lens development. Elavl1 binds to mRNAs encoding key TFs in the lens and its knockout in mice results in eye and lens defects. Together, these findings indicate that Elavl1 plays an important role the development and maintenance of the lens.

ABSTRACT BODY:

Purpose: Herpes simplex virus type-1 (HSV-1) is the leading cause of infectious blindness in the developed world. The current established method of treatment via nucleoside analog acyclovir (ACV) shows significant and effective viral suppression. Trifluridine needs to be administered up to 9 times daily to ensure effective ocular retention of the drug. We have previously uncovered use of drug-encapsulated carbon (DECON) as a sustained drug delivery platform. We have also yet to elucidate the drug loading and release profile and deduce the toxicity of the platform when translated to a living model.

Methods: Activated carbon was pre-weighed and UV sterilized overnight prior to making a 10 mg/mL sterile stock solution in PBS. ACV, PCV, GCV and FCV stock solutions were prepared in DMSO. Drug loading studies were performed in triplicate to assess the deviation between replicates. These samples were analyzed using Mass spectrometry, NMR. ACV loaded carbons were dropped on murine eyes for a period of 4 weeks, once everyday. Murine eyes treated with ACV, carbon, ACV loaded carbon or mock samples were evaluated every week for any signs of toxicity.

Results: In this study, we have evaluated the ability of activated carbon particles to load and sustainably release ACV and 3 other nucleoside analogues using MS. The carbon particles loaded with the drug, termed as DECON were also able to show excellent antiviral activity even when dosed therapeutically at 0.025 mg/mL. Furthermore, we showed that sustained administration of 0.1 mg/mL DECON particles to the eyes and vaginal tissue is very well tolerated and does not cause any unforeseen toxicity. In this regard, we conclude that DECON is a safe, efficacious and cost effective addition to the list of agents for topical delivery of antiviral agents to the ocular tissue.

Conclusions: Carbon-based technologies show promise in the area of targeted drug release in response to certain stimuli. Further research into the ability of DECON's ability to permeate beyond the cornea for release into other ocular tissues may reveal it’s ability to treat pathogens that travel beyond the routes taken by HSV-1 infection.

ABSTRACT BODY:

Purpose: To identify microaneurysms (MA) in optical coherence tomography (OCT) and OCT angiography (OCTA) and explore the relationship between MAs and retinal fluid.

Methods: We obtained four 3×3-mm OCT and OCTA scans with a 400×400 sampling density on one eye of each participant with diabetic retinopathy with a commercial 120-kHz spectral-domain OCT system (Solix; Optovue, Inc.). A projection-resolved algorithm suppressed projection artifacts. A subset of participants also underwent multimodal imaging with color fundus photography and fluorescein angiography, used to identify features of MAs in OCT B-scans and OCT/OCTA en face images. MAs were manually segmented in the OCT and OCTA en face images. We classified MAs as active vs. inactive based on the presence of flow signal within the MA. We compared the amount of fluid in the 0.4mm-diameter circular area including the whole thickness of the retina surrounding the active vs. inactive MAs. A deep learning-based method automatically quantified the fluid volume.

Results: Based on features identified on five eyes that underwent multimodal imaging, [Fig .1], we identified 173 MAs in 35 eyes. MAs were very bright round or irregular spots on OCT en face images [Fig .2 (A)]. Located mainly between the inner nuclear layer and outer plexiform layer, MAs show a strongly reflective wall in OCT B-scans [Fig .2 (C)]. MAs in OCT en face images (2.94±3.20 mm^2) appear larger than in OCTA (1.33±1.15 mm^2, Mann-Whitney U test, $P<0.001$) [Fig .2 (D)]. Seventy-five of 173 had a strong flow signal in OCTA [Fig .2 (B)] and were classified as active. Active MAs had a significantly higher probability of having retinal fluid nearby compared to inactive MA (57/75, 76.00% vs. 59/98, 60.20%, Z test, $P=0.013$). The mean fluid volume near the active MAs (3.63±4.94 mm^3) compared to the inactive MAs (1.09 ±2.46 mm^3) was significantly larger (Mann-Whitney U test, $P<0.001$).

Conclusions: MAs have distinct features on OCT and OCTA images that correlate with observations on multimodal imaging. MAs with flow signals on OCTA are more likely to have associated retinal fluid than those without, suggesting OCTA may identify MAs associated with more leakage.

TITLE: The protective effect of Nicotinamide Riboside on corneal epithelial-stromal injury

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Wang Yee, Y. Chan, K.C. Shih, Y. Bu, H. Mak, J. Yung, Ophthalmology Department, The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: Chu Wang Yee: Commercial Relationship: Code N (No Commercial Relationship) | Yau Kei Chan: Commercial Relationship: Code N (No Commercial Relationship) | Kendrick Shih: Commercial Relationship: Code N (No Commercial Relationship) | Yashan Bu: Commercial Relationship: Code N (No Commercial Relationship) | Heather Kayew Mak: Commercial Relationship: Code N (No Commercial Relationship) | Jasmine Sum-Yee Yung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal epithelial-stromal injuries caused by abrasions or surgical complications deteriorate visual acuity and impede quality of life. Yet, current topical treatments, including Mitomycin-C and corticosteroids, have questionable clinical efficacy and severe side-effects. Nicotinamide Riboside (NR), a precursor to Nicotinamide adenine dinucleotide (NAD+), has been shown to promote wound healing in diabetic mice. We therefore hypothesize that NR serves as a promising novel therapeutic agent to accelerate corneal wound healing by utilizing an experimental pre-treatment mice model of alkali-induced corneal injury.

Methods: C57Bl/6J wild-type female mice 8 weeks of age were topically pre-treated with 500 μM NR on right eye for 7 consecutive days before corneal injury in the experimental group, while phosphate-buffered saline was used for control group. Then, alkali injury was induced on right cornea with NaOH-soaked filter paper with mice under anesthesia, followed by rinsing with filtered water. The left eye was uninjured. Fluorescein staining was used to visualize corneal epithelial-stromal damage with slit-lamp microscopy every 48 hours until Day 6. Stained area was measured with ImageJ and percentage of area healed was calculated. Immunohistochemistry (IHC) of pro-inflammatory and fibrotic markers was also conducted on Day 6.

Results: Based on current data, fluorescein staining showed diffuse epithelial damage after alkali injury in all mice. On Day 2, NR pre-treated corneal epithelium healed by 68.2% (n=3), compared to only 21.7% in control group (n=2). However, opacification was not observed and all corneas achieved full re-epithelialization on Day 4. IHC investigation on Day 6 revealed absence of pro-inflammatory and fibrotic markers Interleukin 1 beta and alpha-smooth muscle actin respectively in both groups.

Conclusions: We have demonstrated NR pre-treatment’s efficacy in accelerating corneal wound healing after alkali injury in the short term, but no difference was found in the long term compared to control. This finding accentuates the potential clinical application of NR pre-treatment in protection against corneal damage. Further investigations with larger sample size are needed to establish a more comprehensive correlation. NR post-treatment after injury is another focus for future investigations.

TITLE: Effect of Fluocinolone Acetonide Intravitreal Implant on Corneal Astigmatism

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Keppel, K. Baynes, S.K. Srivastava, J. Goshe, C. See, Cole Eye Institute, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Kevin Keppel: Commercial Relationship: Code N (No Commercial Relationship) | Kimberly Baynes: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Srivastava: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goshe: Commercial Relationship: Code N (No Commercial Relationship) | Craig See: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The fluocinolone acetonide intravitreal implant has important benefits over systemic corticosteroids and immunosuppression for the treatment of non-infectious uveitis. Its benefits and risks have been well-documented, but recent clinical encounters have potentially revealed a new adverse effect of the implant: surgically induced corneal astigmatism. The purpose of this research is to identify and quantify the degree of corneal astigmatism induced by fluocinolone acetonide intravitreal implantation.

Methods: This was a small retrospective cohort study of 7 patients (8 eyes) that underwent surgical implantation of the fluocinolone acetonide device in the last 10 years. Pre- and post-operative corneal astigmatism values were compared using corneal topographic or keratometric studies that were obtained as part of routine care. For mathematical and statistical comparison, astigmatic magnitudes and axes were converted into power vectors representing both with-the-rule/against-the-rule (WTR/ATR) and oblique components (J_0 and J_{45}, respectively). A third power vector, J_{FA}, calculated the component of corneal steepening in the axis of the implant, assuming standard inferotemporal placement (225°/45° in the right eye and 315°/135° in the left eye).

Results: The mean pre-operative right eye corneal astigmatism was 0.81 D at 51°, while the mean post-operative astigmatism was 1.3 D at 45°. The mean pre-operative left eye corneal astigmatism was 2.9 D at 96°, while the mean post-operative astigmatism was 4.6 D at 103°. J_{FA}, the component of corneal steepening in the axis of the implant, increased perioperatively by an average magnitude across all eyes of 0.60 (P = 0.21). Secondary analysis revealed a non-statistically significant decrease in corneal power (0.8 D, P = 0.06) and increase in astigmatic magnitude (1.7 D, P = 0.08). Of note, there were two outliers in the group that had perioperative cylinder changes of 6.3 D and 4.0 D.

Conclusions: While this study was limited statistically by small sample size, the results still showed notable perioperative corneal changes. It remains to be seen if the eyes with more drastic changes were simply outliers, or if expansion of the sample size will eventually reveal real, statistically significant effects of the surgery on corneal astigmatism. The conclusion of this research may ultimately describe a previously uncharacterized adverse effect of the fluocinolone acetonide implant.

ABSTRACT BODY:

Purpose: The present study aims to describe clinical outcomes after infectious keratitis following penetrating keratoplasty (PKP)

Methods: Retrospective consecutive clinical case series study carried out from 2001 to 2018. Clinical records were reviewed in which subjects with herpetic keratitis with previous PKP were identified. Diagnosis was done following clinical characteristics. Analyzed variables were previous ocular surgeries and medications and ocular surface disease were recorded. Treatment characteristics, indications for surgery and clinical outcomes were also noted. Descriptive statistics, means, and SD were used for continuous variables; percentages were used to describe categorical variables. P, 0.05 was regarded as evidence of significance. All analyses were done with STATA v.10 software.

Results: A total of 22 cases were recorded. Mean age was 43.04 years, 14 patients (63.63%) were male. Mean time of herpetic keratitis after PKP was 35.59 months (2.96 years). Of the 22 cases 19 (86.36%) had just one PKP, 3 patients (13.63%) had 2 or more PKP's. 15 patients (68.18%) had history of herpetic keratitis before the PKP. The main indication for PKP among patients with history of herpetic keratitis were: stromal keratitis in 14 patients (93.33%) and just one case of endothelial keratitis (6.66%). Of the 15 patients who presented herpetic keratitis previous to the PKP only 3 (20%) were on antiviral suppression therapy. Of the 22 patients who presented herpetic keratitis, 17 (77.27%) presented epithelial form and 5 patients (22.72%) presented herpetic keratouveitis .Of the 22 patients, 13 (59.09%) had clear grafts, the remaining 9 grafts were already in failure (40%). 8 (61.53%) remained clear after the event, 5 (38.46%) resulted in marked inflammation, leading to graft failure. Before the infectious event 18 patients (81%) were active steroid users, 4 patients (17.39%) were on prostaglandin analogues and at the time of the event all the patients were treated with: acyclovir 800mg 5 times daily and lubricant drops.

Conclusions: Herpetic infectious keratitis following PKP is an important cause of graft failure. Patients with PKP require close monitoring to identify risk factors for developing infectious keratitis and posterior graft failure. Patients whose transplant was for a herpetic cause, require close monitoring and prompt identification of any visual or graft changes to start appropriate treatment.

TITLE: Evaluating the Qualitative Features of Occular Surface Dry Eye Disease using a Novel Confocal Microscopy Imaging Protocol

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.C. Tsang, J. Nortey, S.E. Lopez, J.A. Gonzales, J.D. Keenan, Francis. I. Proctor Foundation, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Adrian Tsang: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Nortey: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Lopez: Commercial Relationship: Code N (No Commercial Relationship) | John Gonzales: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Keenan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine differences of the corneal sub-basal nerve plexus between participants from the Sjogren's International Collaborative Clinical Alliance (SICCA) and healthy controls based on qualitative features of nerve tortuosity, and the presence of nerve sprouts and dendritic cells.

Methods: Cross-sectional study in which participants from SICCA were recalled for follow-up and age-matched healthy controls were recruited. All participants had in vivo confocal microscopy (Heidelberg Rostock, Heidelberg, Germany) of the central sub-basal nerve plexus centered about the central vortex, yielding a montage image comprised of 30 images. Each image was then assessed by 3 masked graders for 3 features: presence of nerve tortuosity, presence of neuromas, and number of dendritic cells.The majority consensus grade between the 3 graders was calculated for each image, and then the fraction of images per eye with the finding was calculated as a score indicating the proportion of images per eye displaying the given feature.

Results: A total of 774 confocal images from 26 eyes (15 from SICCA participants and 11 control eyes) were reviewed by the 3 graders, with each eye contributing between 25-30 scans. The mean tortuosity score was 40 (SD 27) in the SICCA participant group and 2 (SD 2) in the control group ($P<0.001$, Wilcoxon rank sum test); the mean nerve sprout score was 18 (SD 15) in the SICCA participant group and 2 (SD 2) in the control group ($P=0.04$); and the mean dendritic cell score was 44 (SD 29) in the SICCA participant group and 32 (SD 27) in the control group ($P=0.30$).

Conclusions: The presence of tortuosity and nerve sprouts on in vivo corneal confocal microscopy were significantly different between SICCA participants and healthy controls. There was no significant difference in the amount of dendritic cells between SICCA participants and healthy controls. Our novel imaging protocol can be used to standardize the qualitative evaluation of the corneal sub-basal nerve plexus and the presence of tortuosity and nerve sprouts may be used to differentiate between patients with and without Sjogren's dry eye. Standardized evaluation of the corneal sub-basal nerve plexus may have future applications in the diagnostic criteria for Sjogren's disease and help bring clarity in both the research realm and in the direct care of these patients.

SUBMITTER (NAME ONLY): Pranati Ahuja

TITLE: Impact of Fear of Falling in Adults with Low Vision During the Task of Gait Initiation

SESSION TITLE: Mobility, Reading and Driving with Vision Impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Ahuja, P. Gupta, G. Brusola, T. Chao, R. Welsh, M.E. Schmitz-Brown, M. Ko, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Pranati Ahuja: Commercial Relationship: Code N (No Commercial Relationship) | Praveena Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Gregory Brusola: Commercial Relationship: Code N (No Commercial Relationship) | Tony Chao: Commercial Relationship: Code N (No Commercial Relationship) | Rodney Welsh: Commercial Relationship: Code N (No Commercial Relationship) | Mary Schmitz-Brown: Commercial Relationship: Code N (No Commercial Relationship) | Mansoo Ko: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: 1. Quantify severity of fear of falling (FOF) by comparing temporal characteristics of postural control during the task of Gait Initiation (GI) in healthy adults under the conditions of normal vision, low vision sight simulator (SS), and virtual reality (VR) environment.

2. Assess association of low vision (LV) with changes in postural control during GI.

Methods: 8 adults with LV (mean age 63.3 ± 11.2 y), and 8 age-gender matched healthy adults (mean age 68.1 ± 9.72 yrs) were recruited. All participants performed the task of GI barefoot under normal conditions with 5 trials on a Tekscan™ High Resolution Floor Mat System. Healthy participants performed trials under 2 more conditions: GI with SS, and GI with VR headset (HTC VIVE Cosmos Elite 3D VR system and the Richie's Plank VR experience were used to induce FOF). Absolute temporal events of foot position were obtained from the vertical ground reaction forces corresponding to the swing and stance limbs during GI. To normalize temporal parameters of GI, time from onset of movement to stance limb toe-off was defined as 100% of the GI cycle. The temporal events measured were: 1) time from onset of movement to swing limb toe-off (Anticipatory Postural Adjustment: APA) and 2) time from swing limb heel strike to stance limb toe-off (Double Support Time: DST).

Results: Table 1 and Graph 1 (image) show absolute and normalized temporal data means. Normalized APA during GI with VR headset (47.36% ± 6.50) was similar to GI with SS (46.08% ± 3.11) and normal GI conditions (44.52% ± 4.74) in healthy patients. Normalized APA during GI in LV patients (55.04% ± 5.69) exceeded that for all 3 conditions in healthy patients. Normalized DST during GI with VR headset (32.39% ± 11.74) had much longer duration than GI with SS (23.35% ± 8.93) and normal GI conditions (20.60% ± 2.96) in healthy patients. Normalized DST during GI for LV patients (17.95% ± 3.78) was shorter than that for all 3 conditions in healthy patients.

Conclusions: Both APA and DST for securing the weight shift necessary to execute the first step from a static standing position can be used as objective biomarkers to quantify the severity of FOF. APA values demonstrate that low vision has a similar impact on postural control as VR use in healthy adults, and prolonged DST is observed in healthy adults with induced new-onset FOF during GI.

TITLE: Topical Recombinant Human Nerve Growth Factor for Management of Refractory Epithelial Keratopathy

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: X. Dai, X. Zhu, S. Karakus, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Xi Dai: Commercial Relationship: Code N (No Commercial Relationship) | Xi Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Sezen Karakus: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the effect of topical application of recombinant human nerve growth factor (rhNGF) eye drops in the management of refractory epithelial keratopathy.

Methods: A retrospective chart review was conducted on patients treated with topical rhNGF for a diagnosis of refractory epithelial keratopathy due to neurotrophic keratitis (NK). Patients with epithelial defects or ulcers due to stage II and stage III NK were not included. Data regarding demographics and ocular/systemic past medical history was extracted from patient charts. Visual acuity, corneal, and conjunctival staining scores were recorded at baseline and subsequent follow-up visits along with side effects from treatment as reported by patients. The primary outcome measure was the change from baseline in corneal staining score upon completion of treatment with treatment success defined as complete resolution of corneal staining or near-complete resolution (corneal staining score ≤1).

Results: We included 26 eyes of 14 patients with refractory epitheliopathy due to stage I NK treated with topical rhNGF. After an 8-week course of treatment, the median corneal staining score in the worse eye decreased from 4 to 1 (p=0.001). All patients showed at least one-grade improvement in corneal staining with complete or near-complete resolution in at least one eye of 13 patients, sustained in 6 patients at three months. A better response was observed in eyes with post-radiation NK, LASIK-induced NK, Sjogren's syndrome, and well-controlled diabetes mellitus. Those with chronic use of other topical treatments (such as anti-glaucoma medications with preservatives) and uncontrolled diabetes mellitus demonstrated incomplete responses. Ten patients (71%) reported mild to moderate ocular discomfort from drop application that all resolved after completion of treatment.

Conclusions: Topical rhNGF application for 8 weeks was effective and tolerable in treating refractory epithelial keratopathy due to stage I NK in our small cohort, although the effect was sustained only in patients with certain underlying etiologies at three months. Further studies are needed to determine the optimum treatment dose and duration based on underlying etiology.

TITLE: Adverse Events Following Intravitreal Brolucizumab for Exudative Age-Related Macular Degeneration

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. pakravan, A. Shaheen, V. Chau, J. Lai, V. Patel, N. Yannuzzi, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: parastou pakravan: Commercial Relationship: Code N (No Commercial Relationship) | Abdulla Shaheen: Commercial Relationship: Code N (No Commercial Relationship) | Viet Chau: Commercial Relationship: Code N (No Commercial Relationship) | James Lai: Commercial Relationship: Code N (No Commercial Relationship) | Veshesh Patel: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Yannuzzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Following its approval by the Food and Drug Administration (FDA) for the treatment of exudative age-related macular degeneration (AMD), brolucizumab has been associated with post-injection intraocular inflammation (IOI) and retinal vasculitis in select cases. We aimed to evaluate clinical outcomes and adverse events (AE) following intravitreal brolucizumab administration at a university-based practice.

Methods: The clinical records of all eyes that received intravitreal brolucizumab at Bascom Palmer Eye Institute between December 1, 2019, and April 1, 2021, were reviewed.

Results: 345 eyes of 278 patients received 801 brolucizumab injections, resulting in 20 eyes of 17 patients who developed an AE. The mean visual acuity (VA) of the entire cohort before brolucizumab injection was 20/51. In patients who developed an AE, baseline VA was 20/43, while VA at initial presentation of the AE was 20/76, representing a loss of approximately 3 lines. Of eyes experiencing an AE, the mean number of injections was 2.3, and the interval between the last brolucizumab injection and presentation with the AE was 24.2 days. The most common presenting symptoms in eyes experiencing an AE were blurry vision (60%) and floaters (50%). Intraocular inflammation was the most common AE (75% of all AEs). Of those eyes with inflammation, 29% had iritis, 50% had vitritis, and 21% had both. No eyes were noted to develop retinitis or choroiditis. Ten percent of eyes with IOI also developed epiretinal membrane. Additionally, there were cases of conjunctivitis (5%), venous occlusion (5%), optic neuropathy (5%), and RPE tear (5%). There was no case of retinal vasculitis. In eyes with IOI, treatment included topical steroids (45%), topical and oral steroids (25%), and observation (30%). Of eyes experiencing IOI, the mean VA at last follow-up was 20/59, representing a loss of 1.5 lines. All eyes with IOI had resolution of inflammation by last follow-up examination.

Conclusions: An adverse event was observed in 5.8% of eyes treated with brolucizumab in this university-based practice. The average symptom onset was 24 days after the last injection. Most symptoms resolved after treatment but mean VA in this cohort decreased on average approximately 1.5 Snellen lines from baseline.

TITLE: Therapeutic effect of topical autologous serum on ocular graft-versus-host disease associated dry eyes

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.T. Carreno-Galeano, L. Johns, J. Yin, R. Dana, Massachusetts Eye and Ear, Department of Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Jimena Carreno-Galeano: Commercial Relationship: Code N (No Commercial Relationship) | Lynette Johns: Commercial Relationship: Code N (No Commercial Relationship) | Jia Yin: Commercial Relationship: Code N (No Commercial Relationship) | Reza Dana: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is the most common manifestation of ocular graft-versus-host disease (oGVHD) associated with significant morbidity and reduced quality of life. Persons with oGVHD have been shown to have abnormal corneal sub-basal nerves, which may play a role in the development of the disease. Autologous serum drops (ASD) are used to treat severe refractory DED due to oGVHD; however, no studies to date have investigated the effect of ASD in corneal nerves in patients with oGVHD. In this prospective observational study, we evaluate the changes in symptoms, signs and corneal sub-basal nerve density in patients with oGVHD after the use of ASD.

Methods: We studied patients with moderate-to-severe DED due to oGVHD who had failed to respond to previous treatment including lubrication, anti-inflammatory medications, and punctal occlusion. A comprehensive evaluation was done at 6 and 12 weeks after initiating ASD, including: VFQ-25, SANDE I & II, OSDI, TBUT, Corneal staining, Conjunctival staining, Schirmer Test, IVCM, and Corneal sensation. Exclusion criteria included active ocular allergies, any change in anti-inflammatory or anti-glaucoma regimen, history of contact lens wear or prosthetic replacement of the ocular surface ecosystem (PROSE), and intraocular surgery or ocular laser surgery in the three months prior to enrollment. Repeated measures analysis of variance (ANOVA) were done to test for the significance of changes. Data are reported as mean ± SD.

Results: Twenty patients with moderate-to-severe oGVHD associated DED who initiated ASD were studied. The average age was 63.4 ± 11.2 years. Twelve were female (60%) and eight (40%) male. SANDE I score was lower at 6 weeks (38.4 ± 7.6) and 12 weeks (37.8 ± 8.2) compare to baseline (67 ± 5.3, p=0.001). There were no other significant differences in dry eye symptoms or signs. The corneal sensitivity increased at 6 week (5 ± 1.3) and 12 week (5.3 ± 0.9) follow-up, compared to baseline (3.8 ± 2.1, p= 0.01). There was also a significant difference in SNFL at 6 weeks (11,264.2 ± 5768.5) and 12 weeks (12,028.1± 5,245.8) compare to baseline (10,117.5 ± 5,927.1 mm/mm^2 , p=0.007).

Conclusions: Patients with severe refractory DED due to oGVHD treated with ASD had an increase of corneal sub-basal nerve density after 6 and 12 weeks of treatment as well as improvement of corneal sensitivity and lower frequency and severity of symptoms of DED.

ABSTRACT BODY:

Purpose: Annual diabetic retinopathy (DR) screenings are critical for preventing blindness in patients with diabetes. Our goal was to successfully integrate artificial intelligence-based image interpretation software into a telemedicine-based diabetic retinopathy screening program at primary care clinics.

Methods: The Byers Eye Institute at Stanford (BEIS) partnered with University HealthCare Alliance (UHA) to integrate IDx-DR, an FDA-cleared AI diagnostic system that autonomously detects diabetic retinopathy (DR) in fundus images, into a pre-existing teleophthalmology workflow. Patients without a prior DR diagnosis or a DR exam in the past year were offered the opportunity to have retinal photographs taken at the end of their primary care visit. The AI-human hybrid workflow involves interpretation by the IDx system. Images deemed ungradable by the AI software were then sent for interpretation by a retina specialist at the BEIS reading center. Patients were referred for in-person exam if either the AI or the human reader detected more than mild DR (mtmDR) in the images.

Results: From April 2021 to December 2021, a total of 550 patients with diabetes at four primary care sites opted for DR screening using the AI-human hybrid workflow. Of these, 72 patients screened positive for mild or worse DR (13%) and 425 patients screened negative (77%). Average gradeability ranged by site from between 80% and 90%.

At each site, the percentage of the diabetic patient population up-to-date with recommended eye exams was measured in accordance with the HEDIS measure specification for Comprehensive Diabetes Care (CDC). A target of 67.89% was chosen, reflecting the 90th percentile HEDIS national benchmark. The percentage of patients adherent with annual diabetic eye exams reached a peak of 71.1% across the four sites after integration of AI into the telemedicine workflow. These outcomes demonstrate that integration of the AI-human hybrid workflow resulted in increased patient adherence with annual diabetic eye exams.

Conclusions: An AI-human hybrid workflow for detecting referral-warranted DR was successfully implemented in the primary care setting and resulted in improved patient adherence and quality measures associated with annual diabetic eye exams.

TITLE: Epidemiology of Contact Lens-Related Corneal Disorders in Emergency Room: Data from Nationwide Emergency Department Sample (NEDS)

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Dayananda, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|B. Usmani, S.A. Shah, V. Jhanji, Ophthalmology, UPMC, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Bushra Usmani: Commercial Relationship: Code N (No Commercial Relationship) | Sanjana Dayananda: Commercial Relationship: Code N (No Commercial Relationship) | Syed Mahmood Shah: Commercial Relationship: Code N (No Commercial Relationship) | Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the epidemiology of visits to the emergency room with contact lens-related corneal disorders at a national level and to identify high-risk groups.

Methods: This is a retrospective longitudinal cohort study. National Emergency Department (ED) Sample, a representative sample of all US EDs, was used to determine the incidence and characteristics of corneal disorders in contact lens users presenting to the ED from 2006 to 2017. ICD-9-CM and ICD-10-CM codes for corneal disorder due to contact lens use (371.82 and H1882) were used to identify patients. Incidence was calculated using US National Census Data. Descriptive statistics were calculated, and multivariate regression was used to estimate the changes in incidence and to compare the demographics between patients with and without contact lens-related corneal disorders.

Results: A total of 149,716 ED visits were recorded with a diagnosis of corneal disorder due to contact lens use. The incidence of ED visits with contact lens-related corneal disorder declined steadily from 2010 (6.10 per 100,000 US population) to 2016 (3.51 per 100,000 US population) with most visits consisting of female patients (67%), adult age-groups (68.9%, p-value 0.05), and patients carrying private insurance (56.3%). The most common discharge diagnosis was eye discharge or redness (10.9%), followed by corneal ulcer (3.6%). Patients belonging to the highest income quartiles were more likely to present to the ED with contact-lens-related corneal disorders (adjusted Odds Ratio, 1.21, 95% CI 1.15-1.27) compared to the low-income quartile. Among those who were discharged from the ED, the average charge per patient was $1051.4 (Standard Deviation [SD]= 795.4).

Conclusions: Women, young adults, and patients with low socioeconomic status were found to have a higher incidence of contact lens-related corneal ED visits. Identification of high-risk groups is important for both optometrists and ophthalmologists when prescribing and referring for contact lenses, and devise additional strategies for prevention of further corneal complications and the associated vision loss.

TITLE: Referral patterns and visual sequelae in children with newly diagnosed primary brain tumors

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. smith, L.C. Mehner, Ophthalmology, Sue Anschutz-Rodgers Eye Center, University of Colorado Anschutz Medical Campus in Aurora, Colorado., Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure: casey smith: Commercial Relationship: Code N (No Commercial Relationship) | Lauren Mehner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is well established that tumors such as optic pathway gliomas and suprasellar tumors have high rates of associated visual impairment and are often symptomatic. The potential visual sequelae associated with tumors in other areas of the brain, however, have received little attention to date. The purpose of this study was to better understand current referral patterns among patients with newly diagnosed brain tumors and further categorize any associated visual impairment. This will serve as a baseline as we initiate a new ophthalmic screening protocol for these patients at our institution.

Methods: This was a retrospective cohort study of all children with primary brain tumors diagnosed at our tertiary care facility from January - December 2019. Charts were reviewed for oncologic data as well as ophthalmic data if an evaluation was performed in either the inpatient or outpatient setting. Patients who were initially diagnosed at our institution but received their oncologic care elsewhere were excluded.

Results: Seventy-one patients were diagnosed with a new primary brain tumor and received at least some portion of their oncologic care within the study period. The mean age at diagnosis was 9.24 years. The distribution of pathologic diagnosis is illustrated in Figure 1. An ophthalmology referral was sent for 45 of these patients (63%), and 41 of these were evaluated by an ophthalmologist [11 inpatient only (27%) vs 15 outpatient only (36%) vs inpatient + outpatient (36%)]. Thirty of the 41 patients had some form of visual impairment (73%), including optic nerve abnormalities (41%), decreased visual acuity to <20/40 (10%), abnormal eye movements (strabismus/nystagmus/motility disorders, 48%), decreased color vision (5%), visual field deficits (15%), abnormal pupils (12%), and eyelid/anterior segment abnormalities (17%). One patient underwent strabismus surgery during the study period. Only one patient was referred to low vision services.

Conclusions: The prevalence of visual impairment among patients with primary brain tumors is high, however, referral rates for ophthalmology evaluation remain low. We plan to address this gap in care by instituting a formal ophthalmology referral and screening protocol at our institution.

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a progressive loss of corneal endothelial cells (CECs) that are post-mitotically arrested with limited proliferative capacity. Therefore, wound healing is mainly achieved through cell enlargement and migration. Inhibition of Rho-kinase, a key regulator of cytoskeletal reorganization has been shown to promote cellular migration. The purpose of this study was therefore to investigate the effect of a novel Rho-associated coiled-coil-containing protein kinase (ROCK) inhibitor, ripasudil (K-115) in promoting CEC cell migration on Descemet's membrane in FECD ex vivo.

Methods: Normal and FECD Descemet's membrane-CEC tissues were obtained from cadaveric corneas or patients undergoing Descemet's membrane endothelial keratoplasty (DMEK) surgeries. The tissues were preserved in Optisol-GS and after washing in PBS were stained with Hoechst 33342 for 30 sec and attached to the plastic plates by air drying for 3 min with the endothelial cell side facing up. The tissues were treated with 1uM of K-115 drug and monitored using live cell imaging microscope (Leica DMi8) for 5 hours. Controls were treated with Chen's media without the drug. The images from three biological and three technical replicates were collected per group, and the velocity and displacement of the cells were analyzed using the TrackMate plugin in ImageJ. Mann-Whitney and one-way Anova tests were used for statistical analysis with $p<0.05$ being statistically significantly different.

Results: Mean velocity (pixels/hour±SD) of CECs without the drug was 0.45±0.11 in normal and 0.64±0.21 in FECD tissues; and increased to 0.65±0.20 ($p<0.05$) and 0.82±0.39 ($p<0.001$) with K-115, respectively. Mean displacement (pixels/hour±SD) of the cells from the normal and FECD tissues without the drug was 4.33±2.19 and 6.63±5.8, which increased to 13.49±10.32 ($p<0.001$) and 15.02±13.10 ($p<0.001$) respectively with K-115. Although the fold change in mean displacement between normal and FECD cells did not change significantly following the treatment with K-115, a significantly higher mean velocity ($p<0.01$) was observed in FECD compared to normal cells.

Conclusions: FECD cells migrate faster on the Descemet's membrane following the treatment with K-115 compared to the normal cells, which further provides a promising therapeutic approach for the treatment of FECD using ripasudil after Descemetorhexis without endothelial keratoplasty (DWEK).

TITLE: TGFβ overcomes FGF-induced transinhibition of EGFR in lens cells to facilitate fibrotic posterior capsule opacification

SESSION TITLE: Lens epithelial cell stress and function

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Musil, CHEMICAL PHYSIOLOGY & BIOCHEMISTRY, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Linda Musil: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In order to cause vision-disrupting fibrotic PCO, lens epithelial cells that survive cataract surgery must migrate to the posterior of the lens capsule and differentiate into myofibroblasts. During this process, the cells become exposed to the FGF that diffuses out of the vitreous body. In vivo and in vitro studies have established that such relatively high levels of FGF induce lens epithelial cells to differentiate into lens fiber cells during normal development. It has been a mystery as to how epithelial cells could instead undergo a mutually exclusive cell fate, namely epithelial to myofibroblast transition (EMyT), in the FGF-rich environment of the posterior capsule.

Methods: Western blotting and immunofluorescent microscopy were used to assess the expression of markers of lens cell EMyT in serum-free primary cultures of embryonic chick lens epithelial cells (DCDMLs) grown in the absence or presence of TGFβ and/or FGF. The effect of growth factors on the activation state of ErbBs, AKT, and ERK was assessed using phospho-specific antibodies.

Results: We have previously shown that the ability of TGFβ to induce lens cell fibrosis requires the activity of endogenous ErbBs. We show here that lens fiber-promoting levels of FGF induce desensitization of the ErbB EGFR1 that involves its phosphorylation on T669 mediated by ERK activity. Transinhibition of EGFR1 by FGF is overcome by a time-dependent increase in expression of total and cell surface EGFR1 induced by TGFβ, the active levels of which are increased after cataract surgery.

Conclusions: Together, our studies show how a novel integration of TGFβ, FGF, and ErbB signaling pathways can direct EMyT of lens cells under physiologically relevant conditions. They also provide a rationale for why TGFβ upregulates EGFR1 in these cells, and further support the receptor as a therapeutic target for PCO.

ABSTRACT BODY:

Purpose: Measuring the biomechanical properties of the eye can be useful for understanding structure and assessing ocular health. In particular, the organization of the corneal stroma's extracellular matrix is essential for vision. The presence of Collagen XII in the corneal stroma affects the corneal structure and has been hypothesized to affect biomechanical properties. Here, we use a multimodal optical elastography approach to measure the effect of Collagen XII on the biomechanical properties of the cornea.

Methods: The measurements were performed within 24 hours of eye enucleation (after overnight shipment from Tampa to Houston in corneal preservation media). Age and gender-matched wild type (WT) and collagen XII insufficient corneas were dissected with scleral ring intact and mounted on a closed loop intraocular pressure (IOP) control system. Measurements were taken from 10 mmHg to 25 mmHg in 5 mmHg increments. Figure 1 shows the air coupled ultrasound elastography (ACUS-OCE), heartbeat OCE (Hb-OCE), and Brillouin microscopy systems used to assess the mechanical properties of five corneas of each group. The corresponding Brillouin frequency shift, Lamb wave speed, and compressive strain measured from each technique respectively characterize the mechanical properties of the tissue.

Results: Results of the optical elastography measurements are shown in Figure 2. All measurement techniques show a distinct decrease in stiffness due to collagen XII insufficiency. Furthermore, both OCE techniques show an expected increase in stiffness as a function of IOP; however, this trend was absent in the Brillouin measurements.

Conclusions: Optical elastography can be used to measure the stiffness of the cornea as a function of IOP. Furthermore, measurements suggest that the presence of Collagen XII increases the stiffness of the corneal stroma. Future work will be geared towards the quantification of tissue biomechanical properties, as well as the investigation of tissue anisotropy.

ABSTRACT BODY:

Purpose: The eye provides a direct window to display neuro-retinal disease and the interconnections between the eye and brain may elucidate common features of both neurological and eye diseases. This exploratory, validation clinical study sought to examine vitreous levels of neurodegeneration biomarkers in postmortem eyes and brains of those with Alzheimer's Disease (AD), Chronic Traumatic Encephalopathy (CTE), other tauopathies, and healthy controls.

Methods: We examined 43 donated postmortem eyes and corresponding brains, with the diagnosis of AD, CTE, both AD + CTE, other tauopathies, and healthy controls by Meso Scale Discovery immunoassay to quantitatively measure amyloid-beta (Aβ), total and phosphorylated tau (tTau, pTau), neurofilament light chain (NfL), and eotaxin-1. Kruskall-Wallis Rank sum test and Wilcoxon rank tests were used to determine if vitreous biomarker levels were significantly associated with pathological diagnosis, ADNC, and CTE Staging. Spearman's rank correlation was used to compare biomarker levels in vitreous and cortical tissue.

Results: Vitreous levels of tTau ($p=1.6x10^{-}2$), pTau-181 ($p=6.4x10^{-3}$), and pTau-231 ($p=4.2x10^{-2}$) were significantly associated with pathological brain diagnoses. In pairwise comparisons, significance was found for tTau in AD+CTE (n=9) vs CTE (n=15) ($p=4.8x10^{-2}$) and AD+CTE vs AD (n=7) ($p=4.8x10^{-2}$). NfL ($p=1.7x10^{-2}$, n=33) in the vitreous was significantly associated with CTE Staging. When comparing vitreous levels to corresponding levels of the same biomarkers in cortical tissue, eotaxin-1 ($p=1.3x10^{-2}$, n=32, r=-0.45) and t-Tau ($p=1.0x10^{-4}$, n= 39, r=0.61) were significantly correlated.

Conclusions: Vitreous tTau, pTau-181, and pTau-231 in postmortem eyes significantly correlate with AD and CTE pathology in post-mortem brains, while vitreous NfL was correlated with CTE staging. Additionally, vitreous and cortical tissue levels of tTau and eotaxin-1 were significantly correlated. This study validates prior reports by our group and lends further credence that the eye may serve as a potential source of diagnosis and prognosis of neurodegenerative diseases.

ABSTRACT BODY:

Purpose:

Light-Induced Retinal Degeneration (LIRD) is a powerful method to assess the response of photoreceptors to damage. Traditionally performed using fluorescent lamps on albino animals, this tool is unsuitable for pigmented animals. We wanted to model LIRD in commonly used C57Black mice that carry a hypomorphic RPE65 allele. We came across a previously developed method using LED lamps and mouse cages to create small, inexpensive light damage boxes and have successfully implemented this method to achieve LIRD in C57Black animals.

Methods:

We obtained LED lights to reproduce the >60k lux light intensity reported by a previous study. We adapted them with a 3-D printed fitted lid to securely attach the lights to the mouse cages. The light intensity was adjustable from 5,000 to 63,000 lux with the adjustment of a dimmer switch. Low-noise fans had to be equipped to the boxes. These allowed the boxes to maintain an acceptable temperature range of (25-27°C) while lights were in operation with little disturbance to the mouse. Mice used were C57Black, and 129/Sv reared in cyclic lighting conditions. The eyes were dilated with Tropicamide 1% and Phenylephrine Hydrochloride 2.5% (in a ratio 1:1) 10 minutes before light damage. The light damage was performed between 7-11 pm, at varying light intensities ranging from 20-60k lux after 24hr dark adaptation. The mice were returned to dark for 24hrs following light damage and then were returned to the animal facility and maintained with cyclic light conditions. Electroretinography (ERG) was performed at 24hrs and one week post light damage to evaluate visual function.

Results:

We were able to build light boxes for about $200-300 per box, depending on the prices of LED studio lights, fans, and plastic filament. The lightbox was powerful enough to induce a significant reduction in visual function in C57Black mice following four hours and 129/Sv after only 1 hour of exposure at >60000 lux. The results also indicate that visual function is significantly reduced by 24 hrs and remains reduced at seven days.

Conclusions:

This method allows for a rapid assessment of mice models such as the C57Black or 129/Sv background. In addition, most labs can quickly build the light damage box, which can alleviate some of the barriers to studying retinal disease mice models under light stress conditions.

ABSTRACT BODY:

Purpose: To mathematically model the frequency distribution of county-level vision impairment (VI) prevalence estimates between 2015 and 2019 and assess for geographic disparities. To use machine learning algorithms to test the feasibility of predictive modeling of VI prevalence estimates.

Methods: American Community Survey (ACS) data were used to estimate the county-level prevalence of adult VI in 3220 counties and county-equivalents in the United States for each year between 2015 and 2019. The VI prevalence frequency distribution was assessed for normalcy using the chi-square goodness of fit test. Kurtosis of the frequency distribution was calculated for each year. Machine learning decision tree software was developed in Matlab (IBM, Natick, MA) with a training data set of VI prevalence estimates stratified by age for 2,720 counties from 2014. The training set was used to develop an algorithm to predict the change in vision impairment from 2014-2019 and tested against data from 500 randomized counties held in reserve.

Results: The frequency distribution of vision impairment was not normally distributed for any of the 5 years assessed ($p<0.001$ for each year). Kurtosis ranged from 15.2 to 20.4. Linear regression showed the machine learning algorithm predicted change in VI compared to the actual VI prevalence change with an R^2 coefficient of 0.244. The biggest predictors of change in VI based on the model were the prevalence of VI in the 65 and older age cohort from 2014 and the prevalence of VI in the 18-64 age cohort.

Conclusions: National health surveillance data demonstrate skewed frequency distributions for VI prevalence, indicating vision impairment disparities at the county-level in the United States. This analysis allows identification of locations with disproportionately high VI prevalence and capabilities to monitor changes to that distribution over time. Preliminary machine learning algorithms suggest that predictive capabilities of VI with limited training data are possible.

ABSTRACT BODY:

Purpose: To test the custom orphan pediatric retinal disease panel for its detection in variants in the LRP5 gene. Familial Exudative Vitreo Retinopathy (FEVR) is due to variants that affect various genes including the LRP5 gene. LRP5 (LDL Receptor Related Protein 5) is an essential coreceptor, along with TSPAN12 and FZD4, which makes retinal endothelial cells uniquely responsive to Norrin WNT-signaling. 76 subjects diagnosed with FEVR, and near relatives were sequenced through a custom Ampliseq panel that includes eight genes related to FEVR/Norrie Disease and Retinoschisis (NDP, CTNNB1, TSPAN12, KIF11, FZD4, LRP5, ZNF408, RS1).

Methods:

8 genes were run through a custom Ampliseq targeted panel (180 amplicons) which was designed with the Illumina's DesignStudio Sequencing Assay Designer. The targeted panel was put into three pools (PCR reactions) per patient sample for complete coverage of 83 exons with 25 bp adjacent intron sequence. The targeted genes included: NDP (ChrX), RS1 (Chr10); CTNNB1 (Chr3); TSPAN12 (Chr7); KIF11 (Chr10), FZD4 (Chr11), LRP5 (Chr11), and ZNF408 (Chr11). Then the Ampliseq libraries were sequenced on the Illumina iSeq-100 platform. Through the use of ClinVar and The Genome Aggregation Databases (gnomAD), the variant impacts and allele frequency data was collected.

Results: 33 protein-altering variants were found in six FEVR/ND related genes. Of note, 13/33 (39.4%) of the variants were present in the LRP5 gene. The LRP5 gene is involved in the Wnt signaling pathway associated with FEVR with mutations showing a lack of vascularization to the retina. For the variants, two are found to be pathogenic, 1 novel likely pathogenic and 1 novel variant of unknown significance. 95.5% of the base reads were > Q30 quality, the percent on-target bases passing filer was 92.2%, and the average sequencing depth coverage was 978.

Conclusions: Our custom targeted-sequencing panel was developed in order to detect variants in seven FEVR / Norrie Disease genes. We conclude that this panel provides sufficient depth of sequencing to detect variants in the LRP5 gene (exons and splice sites) and to determine zygosity of variants.

TITLE: Continuously tunable attenuator for vision care with unprecedented contrast ratio

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Li, T. Dai, Y. Sun, Zhejiang Lab, Hangzhou, Zhejiang, CHINA|

Commercial Relationships Disclosure: Guoqiang Li: Commercial Relationship: Code N (No Commercial Relationship) | Tiantian Dai: Commercial Relationship: Code N (No Commercial Relationship) | Yongqiang Sun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Attenuators are basic ophthalmic optical elements. They have wide applications such as sunglasses, treatment of amblyopia, ophthalmic imaging systems, etc. The majority of the attenuators has a fixed transmission coefficient and they are usually made of dielectric, semiconductor, or metallic coatings based on optical interference or absorption effects. Variation of the transmission requires use of different coatings. Photochromic materials can change the transmission based on the light condition of the environment, but it is slow as it may take a couple minutes to change the transmission from bright to dark light conditions. Electrochromic materials can be used to change the transmission continuously. However, its contrast ratio (the ratio of the highest transmission to the lowest transmission) is limited to about 10. The purpose of this study is to investigate a new technique that can continuously tune the transmission with a contrast ratio much higher than 100 while keeping the device transparent and also with high speed.

Methods: In order to achieve the above goal, we have made a liquid crystal device with large tunability of the transmission. A liquid crystal mixture including nematic liquid crystal, chiral dopant, and dichroic dye is sandwiched between two glasses each coated with transparent conductive thin film. The thickness of the liquid crystal mixture is only about 20 mm. An electrical field is applied to the device by applying a voltage less than 20 Vrms. The variable transmission is due to change of scattering and absorption affected by the orientations of the liquid crystals and the dye, which are tailored by the applied electric field.

Results: The transmission of the new electro-optic device can be tuned across a very large range, and a contrast over 200 has been achieved, much higher than the concurrent technologies. The spectrum in the whole visible range is almost flat, which is good. The response time is fast and it is around 200 milliseconds. The device is polarization-independent, i.e., it responds equally to the light with any polarization and it is suitable for vision care.

Conclusions: A tunable optical device with the highest contrast ratio while maintaining its transparency has been reported. It is promising for a lot of ophthalmic applications, including treatment of amblyopia, sunglass, imaging, etc.

ABSTRACT BODY:

Purpose: Atonic pupil has been reported as a rare complication following cataract surgery. We had clinically observed significant decrease in the maximum pupil dilatation following uneventful cataract surgery in patients. The purpose of our study was to prospectively assess if uncomplicated cataract surgery may result in iris dysfunction with reduced or poor dilation and changes in dynamic pupillary response.

Methods: Prospective, single center, IRB approved observational study of pupillary function (using a Colvard pupillometer). Pupil size was measured in ambient room light, under scotopic conditions, and following standard mydriasis prior to and three or more weeks after uneventful cataract extraction by phacoemulsification using an Alcon Infinity unit. Demographics, cataract type and grade, iris color, and cumulative dissipated energy (CDE) was evaluated. Subjects with preexisting conditions predisposing to pupillary dysfunction were excluded.

Results: 75 eyes from 52 subjects were included in the study. 50% of participants were female. The mean age was 71.9 ± 9.7 years (range of 44-92 years). There was a significant reduction in mean mydriatic pupillary dilation post-surgery (-0.73mm±1.12 mm and 10±14%, p=0.030) and a correlation to the CDE (r=0.258, p=0.040). There was up to a 40% reduction in some cases. There was no association with iris color, nuclear cataract density, or age. Analysis of dynamic pupil response data is ongoing.

Conclusions: There can be a prolonged and significant decrease in pupillary dilation following uncomplicated cataract extraction. Poor dilation (<6 mm) or pupillary disfunction can impact examination of the posterior segment and could also possibly impact performance of some multifocal intraocular lenses. The mechanism for pupillary dysfunction is yet unclear, but investigation is ongoing and will be discussed.

ABSTRACT BODY:

Purpose: To determine the incidence of strabismus post plaque brachytherapy and to categorize the type of strabismus into slipped muscle, sensory strabismus, decompensated phorias, cranial nerve palsies, restrictive muscles, or a combination.

Methods: A prospective consecutive case Sseries of patients who were diagnosed with choroidal melanomas between February 2012 and May 2021 were included. Primary outcome data was to identify the incidence rate of strabismus post plaque brachytherapy, and then to classify the type of strabismus. Demographic data included patient age, gender and residing city. Other variables included pre-and-post-operative visual acuity, tumor height, tumor distance from optic nerve and fovea, number of extraocular muscles operated, primary deviation, classifying the type of strabismus into slipped, restrictive, cranial nerve palsy, or sensory strabismus and duration of follow-up post plaque.

Results: 400 patients underwent plaque brachytherapy, and 10/400 (2.50%) were identified to have strabismus. Our results indicated that the most common type of strabismus post plaque was sensory strabismus with 7/400 (1.75%) patients being affected. All 7 patients with sensory strabismus had an exotropia. Slipped muscle was the second most common with 2/400 (0.50%) patients, 1 patient had a hypertropia and the other patient had a hypotropia both corelating directly with the muscle that was removed. Decompensating phoria was the least common type of strabismus with only 1/400 (0.25%) patient being affected, and this patient had a decompensation of the superior oblique.

Conclusions: Incidence of strabismus post plaque is uncommon. Of the 2.50% of patients identified to have strabismus, only 0.50 % were directly related to surgical complications. Others were related to secondary vision loss from plaque brachytherapy. These results match previous studies in the few numbers of patients who end up with strabismus post plaque. Even though multiple extra ocular muscles may be removed for the insertion and removal of plaque, surgery itself is an uncommon cause of strabismus.

ABSTRACT BODY:

Purpose: Distinct from other vascularized composite allotransplantation (VCA), whole eye transplantation (WET) potentially disrupts the blood ocular barrier which could result in increased ocular immunogenicity and associated pathogenesis. We performed orthotopic rodent WET without immunosuppression to assess the immune reaction and rejection response following WET.

Methods: Male 14-16-week-old Lewis (LEW) Allogeneic or Brown Norway (BN) Syngeneic recipients received hemiface/eye grafts from donor BN rats. Changes in graft skin, eye appearance, serum cytokines, ocular tissue gene expression, and histology (Allo=36, Syn=21) were assessed at cross sectional time-points. Longitudinal assessment (Allo=5, Syn=5) was done for corneal thickness by ocular coherence tomography and serum anti-donor specific antibodies (DSA) by flow cytometry. Skin and cornea rejection grades were assigned using the modified Banff VCA scoring system and clinical corneal transplantation scoring. Eyes were stained with hematoxylin and eosin (H&E) and CD3+ T cells were stained by immunohistochemistry. Serum chemokine levels were measured by Luminex and anti-donor antibody responses were detected by flow cytometry.

Results: Corneal rejection scores were higher in Allo vs. Syn group at POD4 ($P<0.01$). Corneal thickness in the Allo group was 2-fold greater ($P<0.01$) than the Syn group on POD6. H&E revealed Allo lymphocyte infiltrate increased with time in the eye, suggesting graded rejection. qPCR revealed significant upregulation of transplant rejection-associated genes, mirroring the observed infiltration in histology. Allo serum CXCL10 significantly increased by POD4. IFN-γ increased on POD5. Comparing DSA before and after WET showed that Allo eyes increased in IgM on POD4 ($P<0.05$) with a peak at POD5 ($P<0.0001$); IgG appeared at POD6 ($P<0.05$), increasing until POD8. Banff scores showed a difference between Allo and Syn skin at POD5 ($P=0.02$).

Conclusions: Our results suggest that allogeneic WET rejection occurs rapidly without immunosuppression, despite the immune privilege potential of the eye. Corneal transparency and serum CXCL10 level increases are early signs of rejection. IFN-γ and Anti-donor IgM increase reflected ongoing rejection. Skin rejection following WET was consistent with other skin containing VCA models. Since the cornea rejects before the skin, it should receive priority as a diagnostic indicator for WET rejection.

TITLE: Clinical Efficacy of Multiple Small Incision Sub-Tenon Ab Interno Xen Implantation in Patients with Primary Open-Angle Glaucoma (POAG)

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Bear, M. Baum, A. Roschke, B. Graham, J. Lee, Clinic, Colorado Eye Institute, Colorado Springs, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Jacob Bear: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Baum: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Roschke: Commercial Relationship: Code N (No Commercial Relationship) | Brianna Graham: Commercial Relationship: Code N (No Commercial Relationship) | James Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study aims to determine the clinical efficacy of performing multiple Xen stent implantations in patients with POAG as determined by intraocular pressure (IOP) reduction and number of IOP-lowering medications needed after surgery.

Methods: 17 subjects (20 eyes) underwent multiple small-incision sub-Tenon ab interno Xen implantation procedures during a period from 2017 to 2022. Outcome measures monitored were IOP and current number of IOP-lowering medications. Data was taken at the preoperative appointment before each Xen implantation and again at all subsequent post-operative appointments. IOP was attained via Goldman applanation tonometry (GAT). All IOP measurements and procedures were performed by a single surgeon.

Results: Average study participant age was 76.66±9.64 years. At preoperative visits mean IOP was 21.02±8.08mmHg. No eyes recorded an IOP of lower than 10mmHg, 6% recorded an IOP ≤12mmHg, 17% of eyes recorded an IOP ≤15mmHg, 36% recorded an IOP of lower than 17mmHg, and 57% of patients recorded an IOP of 20mmHg or higher. At postoperative visits, mean IOP was 12.37±3.56mmHg. All eyes had an IOP under 20mmHg, 89% of eyes recorded an IOP of 17 or lower, 84% recorded an IOP of 15 or lower, 53% recorded an IOP of 12 or lower, and 26% recorded an IOP of 10 or lower. At preoperative visits, 47% of patients were on 2 or fewer IOP-lowering medications, with an average of 2.53±1.41. At most recent postoperative appointments, 84% of patients were on 2 or fewer medications, with an average of 1.89±1.97. Patients most recent visits ranged from 5-49 months with the mean being 22.5±13.94 months.

Conclusions: IOP-lowering effects were still seen for an average of 22.5 months after most recent Xen implantation. After initial ab interno Xen failure, repeating sub-Tenon ab interno Xen placements is likely a viable option for POAG patients based on IOP-reduction and number of continued drops post-procedurally. These effects have been demonstrated 41 months and longer after procedure in some cases, showing the long-term efficacy of repeating the sub-Tenon ab interno Xen insertion surgery.

ABSTRACT BODY:

Purpose: Cellular senescence is implicated in retinal microvascular pathology that drives disease in DME and wet AMD. UBX1325, a novel small molecule Bcl-xL inhibitor, is a potent senolytic agent. This prospective study assessed the safety, tolerability, and disease-relevant activity of a single intravitreal (IVT) injection of UBX1325 in patients with advanced DME and wet AMD.

Methods: A phase 1, open-label, single ascending dose study (www.clinicaltrials.gov NCT04537884) was conducted in 4 cohorts at 0.5, 1, 5, and 10 µg, respectively. 12 patients, 2 with DME and 1 with wet AMD in each cohort, were enrolled. 7 additional patients with wet AMD were enrolled in the 10 µg cohort. Patients with DME or wet AMD meeting best corrected visual acuity (BCVA) criteria, no anti-VEGF for ≥90 days prior to Day 1, and with macular fluid or, for AMD, subretinal (SR) and/or intraretinal (IR) fluid were eligible to be enrolled. Patients received UBX1325 IVT once and followed through 24 weeks. Safety, change from baseline in BCVA and CST through study end were analyzed.

Results: UBX1325 was well tolerated with a favorable safety profile throughout. No dose-limiting toxicities or evidence of inflammation, infection, hemorrhage, or increase in intraocular pressure were observed.

Amongst 8 patients with DME, BCVA improved in 6 at Week 12, and in 5 at Week 24. At Week 24, 62.5% of patients gained ≥5 letters and 50% gained ≥10 letters. CST remained stable through 24 weeks in most patients with DME. Through 24 weeks, 62.5% of patients did not meet rescue criteria (≥75 µm CST increase from trough or ≥10 ETDRS letters decrease from peak) after UBX1325.

Amongst 10 evaluable patients (of 11) with wet AMD, visual acuity was improved in 7 at 4 weeks and in 5 at Week 12 and CST remained stable through 12 weeks. 80% of patients did not meet rescue criteria through 12 weeks. Reduction in SR and IR fluid was also observed. Additional 24-week data will be available for presentation.

Conclusions: A single IVT injection of UBX1325 up to 10 µg was safe and well tolerated in patients with advanced DME or wet AMD, through 24 weeks. Disease-relevant improvements in BCVA, CST, and IR and SR fluid, were observed in treated subjects. These data support further development of UBX1325, a novel senolytic small molecule, for DME and wet AMD.

TITLE: Anti-amoebic activity of RK-7 peptide mimic against Acanthamoeba spp trophozoites.

SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. PEGUDA, R. Kuppusamy, M.D. Willcox, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|R. Kuppusamy, N. Kumar, School of Chemistry, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: HARI KUMAR PEGUDA: Commercial Relationship: Code N (No Commercial Relationship) | Rajesh Kuppusamy: Commercial Relationship: Code N (No Commercial Relationship) | Naresh Kumar: Commercial Relationship: Code N (No Commercial Relationship) | Mark Willcox: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the anti-amoebic activity of the antimicrobial peptide mimic RK-7 against Acanthamoeba trophozoites (infective form) in comparison with chlorhexidine.

Methods: Acanthamoeba amoebicidal, amoebistatic and encystation assays were performed using protocols described in literature. The activity of peptide mimic RK-7 was compared with chlorohexidine against the Acanthamoeba castellanii 044 with concentrations of both ranging from 125μM to 7.81μM. All experiments are performed in duplicate with three independent replicates. Data was represented as mean ± SE and analysed using two sample t-test and two tailed distributions. $p < 0.05$ is considered as statistically significant.

Results: In amoebicidal assays, both RK-7 and chlorhexidine reduced the numbers of trophozoites by 50% at concentrations ranging from 125 to 15.6 μM, with no difference between activities ($p>0.05$). Similarly,amoebistatic assays showed concentrations between 125 to 7.81 μM prevented the growth of trophozoites by between 100-82% for RK-7 and 100-97% for chlorhexidine ($p>0.05$). In the encystment assay, both RK-7 and chlorhexidine inhibited cyst formation by 70% at the lowest test concentration i.e., 7.81 μM. Inhibition of cyst formation at concentrations 62.5 μM and 15.6 μM by chlorhexidine (97% and 86% reduction) was greater ($p=0.025$ and $p=0.04$) than RK-7 (84% and 71% reduction).

Conclusions: RK-7 peptide mimic showed excellent anti-amoebic activity against Acanthamoeba castellanii 044. Future experiments will evaluate the activity of peptide mimic coated onto contact lens against Acanthamoeba spp.

ABSTRACT BODY:

Purpose: Current treatments for wet age-related macular degeneration (AMD) involve regular anti-VEGF intravitreal injections; thus, far less invasive treatment is desired. We developed an inhibitor of microtubule-associated End Binding Protein 3 named EBIN which inhibits pathological calcium releases in endothelial cells and prevents choroidal neovascularization (CNV) in both mouse and non-human primate models of AMD. Since previous work demonstrated progressive decreases in chromatin accessibility in patients with late-stage of AMD, here we analyze the effects of EBIN in chromatin accessibility of different retinal cell types using single nuclei-assay for transposase-accessible chromatin (snATAC) sequencing in non-human primates.

Methods: CNV was induced via laser photocoagulation in monkey eyes. Monkeys then received 30 µL topical formulations of EBIN or vehicle in each eye after laser-induced CNV twice daily for 7 days and once a day for another 14 days. Then monkey retina/choroid were subjected to nuclei isolation used for snRNA- and snATAC- sequencing. Lastly, further bioinformatic analysis and validations of the sequencing data were performed using immunofluorescent staining of CNV lesions.

Results: Using snATAC-seq transcriptome data, we detected 22 distinct clusters corresponding to different retinal cell types characterized via well-known markers. Unknown ATAC clusters were manually characterized by Pearson Correlation using our snRNA-seq data. Analysis of differential peaks within each cluster revealed a widespread opening of chromatin characterized by an increase in promoter peaks in all cell types detected. The change in chromatin accessibility was associated with increased acetylation of lysine 27 of histone 3 (H3K27ac) nuclear signals ($p<0.0001$, $n=4$) but not histone 4 lysine 8 ($p=0.0956$, $n=4$) assessed with immunofluorescent staining of choroidal neovascular lesions. Additional comparison of our snATAC-seq transcriptome data against a published AMD GWAS dataset showed that EBIN does not open chromatin of genes involved in AMD progression (Spearman Correlation = -0.06).

Conclusions: EBIN induces a widespread increase of chromatin accessibility in cells comprising CNV lesions including metabolically active endothelial cells by increasing the acetylation of H3K27. Testing EBIN in clinical trials could provide AMD patients with an alternative non-invasive (topical) treatment.

TITLE: Evaluating a Smartphone-Based Optic Nerve Imaging Device as a Glaucoma Screening Tool in an Outpatient Clinic Setting

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Lin, Z. Markatia, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|A. Mittal, V. Sanchez, N. Patel, R. Robles, R. Blake, S. Iyer, M.B. Sherwood, Ophthalmology, University of Florida College of Medicine, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Benjamin Lin: Commercial Relationship: Code N (No Commercial Relationship) | Zahra Markatia: Commercial Relationship: Code N (No Commercial Relationship) | Ajay Mittal: Commercial Relationship: Code N (No Commercial Relationship) | Victor Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Nikhil Patel: Commercial Relationship: Code N (No Commercial Relationship) | Rafael Robles: Commercial Relationship: Code N (No Commercial Relationship) | Richard Blake: Commercial Relationship: Code N (No Commercial Relationship) | Siva Iyer: Commercial Relationship: Code N (No Commercial Relationship) | Mark Sherwood: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ideally, population based eye screening could be performed by a layperson with minimal training at low cost with image interpretation occurring at telemedicine grading centers. This would be particularly useful in underserved communities in order to identify high risk individuals and best optimize delivery of ophthalmic care. This study aims to evaluate a smartphone-based ophthalmoscope, D-EYE, as a potential screening device for glaucoma.

Methods: Patients presenting to university based primary care and glaucoma clinics were recruited for this study. Clinical charts were reviewed to determine glaucoma status for each eye of every recruited patient. Without pupillary dilation, bilateral optic nerve videos were captured in 30-second-long clips with the D-EYE portable smartphone attachment for fundus photography. Videos were later independently graded by four ophthalmology residents and an ophthalmology intern in a blinded fashion. Grading criteria included the ability to visualize the optic nerve (yes or no), subjective image quality (5 point Likert scale [1 = minimal visibility of optic nerve head, 5 = optimal visibility of optic nerve head]), cup to disc ratio (0.01 to 0.99), and likelihood of referring patients for additional glaucoma care (5 point Likert scale [1 = very unlikely to refer, 5 = very likely to refer]).

Results: Optic nerve video capture was attempted on a total of 236 eyes (210 normal, 26 glaucomatous). A total of 186 of the 236 videos (78.8%) were of sufficient quality to visualize the nerve (163 normal, 23 glaucomatous). The mean image quality score was 3.11 out of 5. The average cup to disc ratio of normal and glaucomatous eyes was 0.299 and 0.420, respectively (intraclass correlation coefficient [ICC] = 0.436). The likelihood of referral of normal and glaucomatous eyes was 1.671 and 2.565, respectively (ICC = 0.509).

Conclusions: This pilot study used a smartphone-based photography system in undilated eyes which minimizes cost and facilitates ease of adoption. There was a moderate degree of inter-grader agreement for videos and, overall, glaucomatous eyes were more likely to be referred for further workup compared to healthy eyes. Agreement between raters and accurate likelihood of referral for glaucomatous eyes may be increased with dilated imaging and more experienced graders.

ABSTRACT BODY:

Purpose: This study's primary objective was to prospectively investigate the association between glaucoma severity and time IOP peaks occur during WDT. The secondary objective of the study was to assess the association between glaucoma severity and the value of peak IOP in WDT.

Methods: A prospective cross-sectional study lasting 6 months, including patients with bilateral primary open-angle glaucoma (POAG) with no ocular hypotensive medications, being followed up in the Ophthalmology sector of Faculdade de Medicina do ABC. The WDT was performed in all patients on the day of the first attendance. The test is characterized by the ingestion of 800 mL of water right after the first IOP measurement (basal) and after the water intake, 3 more measurements are taken every 15 minutes, with a total of 4 IOP measurements in 45 minutes. The peak IOP corresponds to the highest IOP measured in those 45 minutes.

Results: A total of 46 eyes from 23 participants were included in the present study. The mean age of patients was 67.17±9.22 (SD) years and 60.86% were male. Visual Field severity (MD) and retinal nerve fiber layer (RNFL) global thickness showed no statistically significant association with IOP peak time ($p=0.180$). However, there was a significant association between the severity of glaucoma and the value of peak IOP ($p<0.001$), in which every 1 mmHg increase in the maximum value of IOP resulted in a decrease in MD of 1.18 dB and of 1.51 Micra in the of retinal nerve fiber layer (RNFL) global thickness in OCT

Conclusions: The peak IOP value, but not the time it occurs in WDT, was shown to be related to the severity of glaucoma in POAG patients with no history of ocular medications.

ABSTRACT BODY:

Purpose: We have previously reported that corticosteroids can modulate ocular surface mucins gene expression. Fluorometholone acetate is potent lipophilic steroid ester with enhanced cellular and ocular surface penetration. Short-term topical application of ophthalmic fluorometholone acetate is indicated for many inflammatory conditions involving conjunctiva and cornea. Both corneal and conjunctival epithelial cells express membrane-tethered mucins. Since mucin genes have been shown to contain steroid responsive elements, the present study was designed to test whether fluorometholone acetate can modulate ocular surface mucins levels.

Methods: Stratified cultures of human conjunctival and corneal epithelial cells were used. Conjunctival epithelial cells were grown in serum-free low calcium F12/DMEM medium then switched to serum-containing keratinocyte medium for stratification. Corneal epithelial cells were grown on transwell membrane inserts using growth factor-supplemented keratinocyte medium. The cells were exposed to 100nM and 250nM fluorometholone acetate for 24h, 48 h and 72 h. The effect of fluorometholone acetate on mucin 1, 4, and 16 protein levels was quantified using commercially available ELISA kits.

Results: Fluorometholone acetate treatment resulted in a significant increase in mucin 1 levels in stratified human corneal epithelial cells after 24 hours exposure. However, neither the 100 nor 250nM dose cause any notable change in mucin 4 and 16 protein levels in human corneal epithelial cells at any of the tested time points. Furthermore, fluorometholone acetate treatment did not affect protein levels of mucin 1, 4 or 16 in cultured stratified human conjunctival epithelial cells.

Conclusions: Fluorometholone acetate causes a moderate increase in mucin 1 levels in human corneal epithelial cells but does not modulate mucin 4 or 16 protein levels in human corneal and conjunctival epithelial cells.

ABSTRACT BODY:

Purpose: Uncorrected refractive error such as myopia is a global healthcare burden. If detected early, it is a treatable condition, ultimately preventing amblyopia and reducing the risk of severe ocular complications. The inherent smartphone-camera-lens, with built-in flash presents as an affordable and convenient photorefraction device for large-scale vision screening programs. This study evaluated the application of smartphone photorefraction for pediatric vision screening compared against the autorefraction technique, before and after cycloplegia (pupil dilation).

Methods: A total of 141 Chinese schoolchildren (ages 7 to 14 years old) were recruited in this study. Participants' refractive errors were measured by an optometrist using auto-refraction and the smartphone technique under non-cycloplegic (dry) and cycloplegic (wet) conditions. The smartphone camera was employed to capture eye images at different orientations by rotating the smartphone around four distinct meridians (at vertical 90^{o}, oblique 45^{o}/135^{o}, and horizontal 180^{o} orientations). Refractive error was calculated based on pupil diameter size and crescent image width using conventional theory-based approach. A cross comparison of the transcribed autorefractor reading with photorefraction results was made.

Results: The refractive error measured by autorefractor (ranging from +0.50 D to -12.00 D) were compared among photorefraction results along the four meridians. The correlation r were 0.88 and 0.80 for non-cycloplegic and cycloplegic photorefraction, respectively. The overall mean absolute error (MAE) was smaller under non-cycloplegic conditions (0.65 D vs. 0.84 D). In addition, for dry photorefraction, 79.2% fell within a MAE of +/- 1.00 D compared to 70% for wet photorefraction. Both methods demonstrated an overall sensitivity of >97% in estimating myopic values greater than -1.50 D while the specificity was higher in dry photorefraction (dry: 78% vs wet: 72%).

Conclusions: Our results suggest that smartphone photorefraction has good correlation with auto-refraction, particularly under non-cycloplegic condition. The smartphone method yields as reliable and sensitive measures to detect myopic refractive errors compared with the autorefraction, thereby offering a promising low-cost option for refractive error screenings in poverty-ridden areas of the world.

Brintz: Commercial Relationship: Code N (No Commercial Relationship) | Rachel G. Simpson: Commercial Relationship: Code N (No Commercial Relationship) | Jeff Pettey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe gender representation at eight national ophthalmology conferences, stratified by role, session category, and sub-specialty.

Methods: Design: Retrospective cross-sectional study.

Study Population: 3,053 presenters at the 2019 American Academy of Ophthalmology subspecialty days, American Society of Cataract and Refractive Surgery, American Glaucoma Society, American Society of Retina Specialists, American Society of Ophthalmic Plastic and Reconstructive Surgery, American Association for Pediatric Ophthalmology and Strabismus, North American Neuro-Ophthalmology Society, and American Uveitis Society meetings.

Main Outcome Measures: Gender of presenters in seven sub-specialties stratified by category and role.

Results: The proportion of female presenters was lower than the ABO-estimated proportion of women in their respective fields in cornea (24.4% vs. expected 26.0%), glaucoma (28.0% vs. 39.8%), neuro-ophthalmology (35.6% vs. 45.3%), and pediatrics (41.9% vs. 53.3%) and greater than expected in oculoplastics (36.7% vs. 34.7%), retina (24.3% vs. 19.8%), and uveitis (59.1% vs. 49.1%). For clinical sub-specialty sessions, the proportion of female leaders exceeded the overall proportion of female leaders in the respective sub-specialty in cornea (35.1%, 95% CI: [30.3%, 40.1%] vs. 24.4% all sessions), glaucoma (38.5% [29.6%, 48.1%] vs. 28.0%), pediatrics (63.9% [55.4%, 71.6%] vs. 41.9%), and uveitis (74.2% [56.2%, 86.5%] vs. 59.1%). Females represented fewer than the expected number leaders of surgical sessions in cornea (21.6% [19.6%, 23.9%] vs. 24.4%), glaucoma (18.0% [13.1%, 24.1%] vs. 28.0%), oculoplastics (35.2% [26.7%, 44.8%] vs. 36.7%), pediatrics (22.0% [14.3%, 32.2%] vs. 41.9%), retina (17.7% [13.3%, 23.1%] vs. 24.3%), and uveitis (40% [10.0%, 80.0%] vs. 59.1%). These findings were not statistically significant for retina or uveitis.

Conclusions: Gender representation varied, with fewer than expected female presenters in cornea, glaucoma, neuro-ophthalmology, and pediatrics. Females led relatively more clinical sessions, but were vastly underrepresented in surgical sessions, in all sub-specialties.

TITLE: Tbr2 regulates melanopsin expression in adult ipRGCs and influences their survival after optic nerve crush

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Abed, D. Feldheim, Molecular, Cell, and Developmental Biology, University of California Santa Cruz, Santa Cruz, California, UNITED STATES|

Commercial Relationships Disclosure: Sadaf Abed: Commercial Relationship: Code N (No Commercial Relationship) | David Feldheim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The transcription factor Tbr2 is expressed in intrinsically photosensitive retinal ganglion cells (ipRGCs) and is required during development for their viability, however its role in adult ipRGCs is not clear. Additionally, ipRGCs survive better than conventional RGCs (cRGCs) after optic nerve injury for reasons that are not well understood. We tested the following hypotheses: 1) Tbr2 is required for the maintenance of ipRGCs, 2) Tbr2 can induce expression of ipRGC-specific proteins (the photopigment melanopsin) in cRGCs, 3) Tbr2 is necessary for ipRGC survival after optic nerve injury.

Methods: 1) We administered tamoxifen to adult $Tbr2^{CreER/flox};R26^{tdTomato}$ mice to remove Tbr2 from $Tbr2^{+}$ RGCs while simultaneously labeling their somas, dendrites, and axons with tdTomato. Controls are littermates lacking the floxed Tbr2 allele ($Tbr2^{CreER/+};R26^{tdTomato}$). We analyzed brains (coronal sections) and retinas (flatmounts and sections) >30 days after tamoxifen administration.

2) We injected one eye intravitreally with a virus containing Tbr2 and GFP, and the contralateral control eye with a virus containing GFP alone in wildtype, Tbr2-CKO, $Tbr2^{CreER/flox};R26^{tdTomato}$, and $Tbr2^{CreER/+};R26^{tdTomato}$ mice and analyzed their retinas 2-5 weeks later.

3) We performed the optic nerve crush (ONC) procedure in adult tamoxifen-induced $Tbr2^{CreER/flox};R26^{tdTomato}$ and control mice and analyzed their retinas 2 weeks later.

Three or more mice were used per experimental condition. Images were taken with an Olympus BX51 microscope. 4-8 fields of view (446.15 µm x 333.33 µm) per retina were imaged for quantification. Cells were manually counted in FIJI. Statistical analyses (Student's t-test or two-way ANOVA) and graph generation were performed using GraphPad's Prism9 software.

Results: Loss of Tbr2 in adult $Tbr2^{+}$ RGCs does not affect their viability but results in loss of melanopsin expression (23.5±10 vs. 95.8±6 cells/mm^2, $P<0.001$). Tbr2 is able to induce melanopsin expression in Tbr2 RGCs ($P=0.0156$) but not in Tbr2-deficient RGCs ($P=0.2651$). We find that there is decreased survival of Tbr2-deficient RGCs relative to $Tbr2^{+}$ RGCs after optic nerve crush ($P=0.0153$), however, Tbr2-deficient RGC survival is still greater than the survival of cRGCs ($P=0.007$).

Conclusions: Our findings demonstrate important roles for Tbr2: its regulation of melanopsin expression and its involvement in RGC survival after ONC.

ABSTRACT BODY:

Purpose: To investigate the effect of GAGs on the ECM expression and deposition of hTM cells cultured on 3D natural biopolymer scaffolds and the role of Dex on its remodeling under static and dynamic conditions.

Methods: Anisotropic porous scaffolds were fabricated from natural biopolymers present in the TM extracellular matrix, specifically collagen and a variety of glycosaminoglycans (GAGs), to allow the study of hTM cells' response to extracellular environment composition. 100,000 hTM cells were seeded on the scaffolds and cultured for up to 2 weeks in the presence and absence of 100 nM dexamethasone (Dex). Dynamic 3D cell culture was performed on scaffolds housed in a perfusion chamber connected to a peristaltic pump. mRNA expression levels of elastin, laminin, and MMP-2 were quantified using qPCR. ECM protein deposition was visualized using confocal microscopy. Pressure changes were measured using pressure transducers connected to the dynamic cell culture constructs.

Results: hTM cells cultured on the collagen-only (CO) scaffolds expressed significantly higher amounts of mRNA for the studied ECM proteins compared to hTM cells seeded on tissue culture dishes. The expression of these ECM proteins was also impacted by the composition of those scaffolds. In particular, the addition of chondroitin sulfate (CS) increased the expression of these proteins by up to 8-fold when compared to CO. Dex increased the expression of elastin and decreased expression of laminin and MMP-2 after two weeks of culture in scaffolds. The morphology of elastin and laminin proteins was also impacted as a result of dexamethasone addition. Pressure measured across the scaffolds was higher in cells cultured in the presence of Dex as compared to non-treated controls.

Conclusions: Extracellular matrix remodeling has been shown to play an important role in the IOP homeostasis, increasing the aqueous humor outflow resistance of the TM. Our results show collagen and GAGs are important in providing signals to the cells for the expression of important ECM proteins. CS can potentially be responsible for the promotion of elastin fiber formation. Our results suggest that the presence of GAGs decreases the expression of laminin likely via the integrin pathway when cells are cultured in the presence of Dex. Increased pressure across scaffolds is a result of decreased MMP-2 expression and its effect on ECM protein degradation.

ABSTRACT BODY:

Purpose: Risuteganib (RSG) is a therapeutic peptide in clinical trials for various retinopathies. A Phase II trial in dry age-related macular degeneration (AMD) reported therapeutic effects with no drug-related adverse events [1]. In the oxygen-induced retinopathy (OIR) mouse model, RSG mitigated neovascularization and lowered mRNA of angiogenic and inflammatory processes [2]. In human cell studies, RSG protects Retinal Pigment Epithelium (RPE) cells from dysfunction under oxidative stress [3-5]. Here, we report RSG binds preferentially to the RPE in the retina of an aged (14 mo), but not a young (7 mo), BALB/c mouse.

Methods: Sulfonated-Cy5 was used as it gives lower nonspecific staining in murine retinal tissue sections than TAMRA, Cy5 and AlexaFluor 555. Sulf-Cy5 was conjugated with two different peptides: RSG and a negative control, denoted RGE, similar to RSG in size, hydrophilicity and charge. Two aspects of the staining protocol were tested: staining environment and peptide-dye concentration. Three staining environments were compared: DI water, PBS with Ca^{2+} and Mg^{2+}, and homogenized porcine vitreous humor (HVH). In each of these, 5mM and 20mM solutions were prepared for dye-RSG and dye-RGE. The twelve resulting solutions were used to stain 10mm-thick retina sections of BALB/cJ mouse, either 7 mo or 14 mo old (comparable to 20-30 or 50-60 yr old human, respectively).

Results: Among three different staining environments tested, HVH minimized non-specific staining. Mouse age showed a significant effect: retinal sections from a 14-mo-old mouse consistently showed RSG-specific staining at the RPE at 5μM in HVH (n = 2-3 sections). At 20μM, sulf-Cy5-RSG stained RPE and photoreceptor (PR) layers. Some retinal tissue sections of a 7-mo-old mouse were preferentially stained at the RPE, but not consistently nor peptide-specifically (n = 2-3).

Conclusions: The results show an age-related specific interaction of RSG with the RPE. These findings are consistent with the hypothesis that RSG supports RPE function, which may underlie its therapeutic effects.

TITLE:

A Novel Study of the Extraocular Recti Muscle Degree Orientation: A Cadaveric Approach

SESSION TITLE: Mechanisms of Refractive Error and Eye Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Barton, E. Kim, J. Tanzer, Brown University Warren Alpert Medical School, Providence, Rhode Island, UNITED STATES|V. Rana, J. Schaefer, Department of Ophthalmology, Brown University Warren Alpert Medical School, Providence, Rhode Island, UNITED STATES|

Commercial Relationships Disclosure: Andrew Barton: Commercial Relationship: Code N (No Commercial Relationship) | Viren Rana: Commercial Relationship: Code N (No Commercial Relationship) | Eric Kim: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Tanzer: Commercial Relationship: Code N (No Commercial Relationship) | Jamie Schaefer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

The anatomy of the extraocular rectus muscle insertions are clinically relevant in the field of ophthalmology. This descriptive cadaveric study determines relative degree orientation of the superior, lateral, and inferior recti with respect to the medial rectus, as well as investigating the distances between the rectus muscle insertions.

Methods:

30 cadavers (50% female, mean age = 81.86 years, SD 12.16) were included for a total of 60 eyes. For each eye, a lateral canthotomy with superior and inferior cantholysis was performed followed by a peritomy. Muscle hooks were then used to access and isolate the recti muscles. The degree orientation was determined by marking the muscle midpoints at insertion, using the center of the cornea as the vertex, and measuring the angle with the Angle Meter app (Fig. 1). The distances between recti were measured from the same muscle midpoints at insertion using calipers.

Results:

The degree orientations with respect to the medial rectus are displayed in Figure 2, and were as follows: superior rectus (mean = 93.14, SD = 3.04, min. 82.3, max. 100.3), lateral rectus (mean = 180.21, SD = 5.65, min. 170.5, max. 190.6), and inferior rectus (mean = 90.57, SD = 4.47, min. 84.0, max. 98.9). The distances (measured in mm) between recti muscle midpoints at insertion included medial rectus to inferior rectus (mean = 13.64, SD = 0.54), inferior rectus to lateral rectus (mean = 13.79, SD = 0.75), lateral rectus to superior rectus (mean =13.54, SD = 0.63), and superior rectus to medial rectus (mean = 13.83, SD = 0.75).

Conclusions:

This is a novel study of the extraocular muscle degree orientation performed with an innovative measuring approach. We found the recti degree orientation to approximate right angles between each muscle, however, there was wide variability. The mean distance between rectus muscle insertions were nearly uniform.The degree orientation of the insertions relative to the medial rectus have not been previously reported and may have surgical application in the field of ophthalmology.

ABSTRACT BODY:

Purpose: Primary cilia are microtubule-based organelles that are found on differentiated cell types throughout the body. Proper cilia formation is critical during eye development in humans and rodents; ciliary dysfunction can result in wide-ranging ocular diseases. Our previous papers support both amacrine and retinal ganglion cells (RGC) harbor primary cilia in primate and mouse retina. However, whether primary cilia patterning changes during retinal development remains unknown. The purpose of this study is to describe the primary cilia distribution in hESC (human Embryonic Stem Cell)-derived retinal organoids.

Methods: Retinal organoids were differentiated from the Brn3b-Tdtomato hESC line and collected at different developmental stages (w6-w38) and immunostained for the presence of cilia. Three ciliary markers, including Arl13b, AC3 and Centrin3 were used to identify primary cilia. Chx10, PKC2a, Prox1, GFAP, AP2a GAD67, Calretinin antibodies were used to determine retinal cell types. Arl13b stained the axoneme while Centrin3 marked the basal body. Statistical analysis was performed using One-way ANOVA and Student t-test.

Results: A group of ciliated cells localized in the inner aspects of retinal organoids cultured w7 to w34 (n=3-5 per time point). At w38, the number of primary cilia among non-photoreceptor retinal cell was significantly decreased compared to w13 (n=5, $p<0.001$). Furthermore, there were very few ciliated Prox1-positive horizontal, GFAP-positive astrocytes and PKC2a-positive rod-bipolar cells at w38 or w25. For AP2a-positive amacrine cells, we found ciliation was stable among all stages of retinal organoids (n=3 per timepoint). Ciliation significantly decreased for Brn3b-positive RGCs at later timepoints (n=5). Additionally, AC3-positive ciliation in non-RGC retinal cells at w25 significantly decreased as compared to w9. AC3-positive ciliation in Brn3b-RGCs decreased by w25.

Conclusions: These novel findings indicate amacrine cells incorporate stable ciliation whereas the RGC ciliation decreased along retinal organoid development, suggesting primary cilia potentially play significant roles for RGC survival in the retinal organoid.

ABSTRACT BODY:

Purpose: To determine surgical outcomes of trabeculectomy for patients with low preoperative intraocular pressure.

Methods: The retrospective cohort study included patients requiring trabeculectomy(TB) with mitomycin C with preoperative intraocular pressures(IOP) less than 15mmHg from March2006 to May2017. Patients with at least 1 year follow-up in the post-operative period were included. Demographic and clinical data were collected at the preoperative visit and post-operative visits for up to 7 years. Surgical failures were defined as eyes that required reoperation or progressed to no light perception.

Results: Forty eyes of 31 patients met inclusion criteria. Mean patient age was 75.2±9.3 years old and mean follow-up duration was 61.2±23.0 months(range: 14-93). 6(15%) eyes experienced surgical complications:2(5%) bleb leak,4(10%) scarred/encapsulated trabeculectomy blebs. 4 eyes developed IOP less than 6mmHg; however, none developed hypotony related complications.10(25%) eyes were documented to have failed TB with a mean duration of 29.5±28.2 months prior to failure. All failure(100%) were due to the need for reoperation secondary to inadequate IOP control: 8(20%) tube shunt, 2(5%) repeat TB,1(2.5%) CyPass microstent.1(2.5%) eye required 2 reoperations including a repeat TB followed by CyPass microstent. Mean IOP between preoperative and each post-operative visit was not significantly different, which was 12.7±2.7 preoperatively and ranged from 11.4±3.3 to 12.2±4.3 mmHg postoperatively for up to 5 years($p>0.05$ for all). Humphrey 24-2 visual field(VF) mean deviations(n=11) were not significantly different at -12.9±7.2 and -12.9±8.2($p=1$) during the most recent preoperative and postoperative visits, respectively. 24-2 mean slopes were significantly different at -1.3±1.8 and 1.4±3.8($p=0.012$) during the preoperative and postoperative periods, respectively. Octopus 30-2 VF mean defects(n=9) were not significantly different at 11.1±7.1 and 12.6±9.9($p=0.385$) at the most recent preoperative and postoperative visits, respectively. 30-2 mean slopes were not different at 1.4±2.0 and 0.45±2.1($p=0.445$) during the preoperative and postoperative periods, respectively.

Conclusions: Although the IOP was not significantly lower than low-normal preoperative IOP, there was no significant progression on VF. Mean deviation/defect remained stable and 24-2 mean slope even showed possible slowing of glaucomatous VF progression.

ABSTRACT BODY:

Purpose: To investigate the correlation between the morphology, autofluorescence and sensitivity of photocoagulated lesions in patients with proliferative diabetic retinopathy (PDR) with good vision.

Methods: Patients with PDR (n=17) who visited Osaka University Hospital from April 2019 to October 2021 and underwent panretinal photocoagulation more than one year ago (BCVA≧0.8) were included. Maintenance of the circulation of photocoagulation scars was confirmed by optical coherence tomography (OCT) angiography (Angioplex Elite 9000), while autofluorescence of photocoagulated lesions were evaluated using ultra-widefield retinal imaging (Optos: TX-200). The scars were then classified according to levels of autofluorescence—group A for those with no autofluorescence, group B for those with remaining autofluorescence, and group C as control. OCT (Spectralis) was used to evaluate the ellipsoid zone (EZ) lines of the photocoagulated lesions.

Results: The retinal sensitivities of photocoagulated lesions were 3.3±5.0dB, 15.3±4.4dB and 21.8±2.4dB for groups A (n=35), B (n=37) and C (n=32), respectively, while the percentages of remaining EZ lines were 5.7%, 81.1% and 100%, respectively. There are significant statistical differences ($P < 0.05$) in both the retinal sensitivities of photocoagulated lesions and the percentages of remaining EZ lines.

Conclusions: The photoreceptors in photocoagulated lesions with autofluorescence retain morphology and some function.

ABSTRACT BODY:

Purpose: Using a novel atlas-based segmentation method, we aimed to identify whether specific orbital soft tissue volumes in patients with thyroid eye disease (TED) correlated with patient and clinical characteristics.

Methods: A retrospective chart review was performed to identify patients with a diagnosis of TED who had been evaluated clinically by an oculoplastic surgeon and had a CT scan of the orbits. Patient characteristics included age, sex, race, smoking status, and body mass index (BMI). Clinical characteristics including Clinical Activity Score (CAS) and strabismus were evaluated with respect to soft tissue volume measurements for each extraocular muscle (EOM) and orbital fat. Statistical analyses were performed using R software (version 4.0.3). Multiple regression analysis and Pearson's correlation were used to evaluate data. Significance was defined as $p<0.05$.

Results: 37 patients were evaluated (22 female, 15 male). CAS ranged from 0-5, and 7 patients had documented strabismus. There was no statistically significant correlation between orbital EOM volumes and age (p=0.382), sex (p=0.808), race (p=0.623), smoking status (p=0.684), or BMI (p=0.744). Furthermore, there was no statistically significant correlation between orbital fat volume and age (p=0.520), sex (p=0.934), race (p=0.640), smoking status (p=0.695), or BMI (p=0.700). Overall, EOM and orbital fat volumes showed high correlation with each other (Table 1). However, there was no statistically significant correlation between EOM volumes and CAS (p=0.483) or strabismus (p=0.174); there was also no statistically significant correlation between fat volume and CAS (p=0.514) or strabismus (p=0.163).

Conclusions: There is no significant correlation between orbital soft tissue volumes and patient characteristics (age, sex, race, BMI), and surprisingly no correlation with smoking status (a known risk factor for TED) among patients in our TED cohort. While orbital soft tissue volumes show high correlation with each other, they collectively do not correlate significantly with clinical characteristics such as CAS and strabismus. For CAS, this finding is not entirely unexpected as CAS is a measure of activity rather than severity; for strabismus, this implies there may be qualities other than orbital soft tissue volume which are important in determining strabismus.

ABSTRACT BODY:

Purpose: Purpose: Keratoconus(KC) is a progressive, corneal, ectatic disorder characterized by increased MMP9 and reduced Lysyl oxidase(LOX) in patients. To rescue LOX expression and inhibit inflammatory signaling, we tested an MMP inhibitor Batimastat(BST) and the inflammation regulator Trehalose(TRE).

Methods: Methodology: Corneal stromal lenticules from donors undergoing SMILE refractive surgeries were treated with TRE and BST for 3 weeks and assessed for expression of LOX, MMP9 and Collagens under chronic inflammatory stress. Primary fibroblasts(HCF) derived from control and KC corneas were analyzed for gene/protein expression and collagen gel contractility when treated with BST/TRE. Human corneal epithelial cells(HCE-T) under chronic inflammation with and without BST/TRE treatment were assessed for LOX, Collagens, MMP9 and phosphorylated MAPK(p38), NFκB(p65) and AKT by immunoblotting.

Results: Results: Inflammatory stimuli significantly enhanced MMP9 and reduced LOX levels in ex-vivo donor stromal lenticules and well as corneal cell types. TRE and BST treatment significantly reduced MMP9 levels which consequently increased LOX and Collagen expression in lenticules under basal and inflammatory stress. Donor control HCF and KC-HCF treated with BST significantly increased LOX levels as well as collagen gel contraction. TRE and BST treatment reduced phosphorylation of p65 and p38 under chronic inflammatory stress in HCE-T cells leading to significantly enhanced LOX and Collagen expression.

Conclusions: Conclusion: Chronic inflammatory signalling including excess MMP9 production transcriptionally suppresses LOX production in corneal stroma. Since TRE and BST rescued LOX and Collagen expression while inhibiting MMP9 via p38 and p65 pathways, they may be a novel therapeutic modality for KC.

ABSTRACT BODY:

Purpose: Retinal signalling appears to be important in the process of emmetropisation. A large number of genetic loci associated with myopia risk have now been identified. We explored associations between myopia-risk polymorphisms and light-adapted flicker electroretinogram (ERG) responses recorded in healthy adult twins.

Methods: This study analysed light-adapted 30 Hz flicker ERG peak times recorded in two non-overlapping cohorts recruited from the TwinsUK registry. Cohort 1 comprised 786 genotyped subjects who had undergone non-mydriatic ERG recording with skin electrodes (RETeval system, LKC technologies, Gaithersburg, MD) to stimuli designed to deliver retinal illuminance equivalent to the international standard 30 Hz ERG. Cohort 2 comprised 185 twins who had undergone conventional standard mydriatic 30 Hz ERG recording (Colordome, Diagnosys LLC, Lowell, MA) with conductive fibre electrodes following mydriasis and at least 10 min light adaptation to the standard light-adapting background. Phenotypes were normalised and standardised. Linear mixed models, adjusting for age, sex and familiar relatedness were used to test associations between 334 myopia risk loci and ERG peak times (Cohort 1). Associations of interest were then tested specifically in Cohort 2. We pooled the results from each through a fixed-effect inverse variance meta-analysis.

Results: No genetic associations reached statistical significance after correction for multiple testing in Cohort 1. However, one of the loci reaching nominal significance was rs13268738 (p=0.0148) which is within the CNGB3 gene, encoding one of the subunits of the outer segment cation channel which underlies the cone photoreceptor electrical response to light. This single association was tested in ERGs from Cohort 2 and found to be significant (p=0.00526). The direction of associations was consistent, and it became more statistically significant after a meta-analysis.

Conclusions: Although the association was only nominally significant in Cohort 1, the replication in Cohort 2 strengthens the evidence that this locus is associated with retinal cone-driven flicker responses in healthy individuals. The findings are consistent with alterations in cone-driven signals playing a role in myopia development.

TITLE: Commercially available, unmodified Octopus perimeters can characterize rod-photoreceptor function in two-color dark-adapted perimetry

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Everett, A.D. Igelman, P. Yang, M.E. Pennesi, Ophthalmology, Oregon Health & Science University, Portland, Oregon, UNITED STATES|J.C. Park, R.A. Hyde, J. McAnany, Ophthalmology, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Lesley Everett: Commercial Relationship: Code N (No Commercial Relationship) | Austin Igelman: Commercial Relationship: Code N (No Commercial Relationship) | Jason Park: Commercial Relationship: Code N (No Commercial Relationship) | Robert Hyde: Commercial Relationship: Code N (No Commercial Relationship) | J Jason McAnany: Commercial Relationship: Code N (No Commercial Relationship) | Paul Yang: Commercial Relationship: Code N (No Commercial Relationship) | Mark Pennesi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Two-color dark-adapted perimetry (2cDAP) is an emerging clinical tool for characterizing the pattern of rod versus cone-dependent deficits across a patient's visual field; 2cDAP has become important in gene-therapy clinical trials given its ability to localize and quantify changes in rod-driven responses. However, custom modifications of static perimeters are often made, limiting their widespread use and comparability across clinical sites. This observational clinical study tested the hypothesis that a commercially available, unmodified Octopus 900-Pro perimeter can characterize rod function by detecting a 2 log-unit difference in retinal sensitivities in healthy subjects between blue and red (450 nm and 610 nm wavelength) stimuli, as expected based upon validated spectral sensitivity curves.

Methods: Ten healthy volunteers with no retinal pathology participated in this IRB-approved study (23-60 years old; 3 females). Subjects were tested with standard (unmodified) Octopus 900-Pro perimeters at the Casey Eye Institute (CEI, n=4) and the Illinois Eye and Ear Infirmary (IEEI, n=6). Testing of the right eye with appropriate refractive correction for measurements within the central 20-degrees of the visual field was performed (left eyes were patched). Fifteen locations from 45^{o} nasal to 60^{o} temporal were tested along the horizontal meridian of the visual field using a Goldmann III stimulus. Testing parameters and statistical analysis were performed as previously described.

Results: An unmodified Octopus 900-Pro perimeter utilized at two clinical sites successfully detected an approximately 2-log difference in threshold values for blue compared to red stimuli outside of the fovea in healthy subjects (Figure 1), which corresponds to the expected difference for rod sensitivity to blue vs red stimuli based on spectral sensitivity curves. In the rod-free fovea, red and blue thresholds were equivalent, consistent with the cone-pathway mediating foveal sensitivity.

Conclusions: Commercially available, unmodified Octopus 900-Pro perimeters may be used to reliably measure rod-photoreceptor function. Thus, custom device modifications are likely not necessary for most clinical and research evaluations of retinal degeneration patients, including potentially for monitoring disease progression and response to gene-based therapies.

TITLE: Phototranduction noise in rods controlling visual detection threshold.

SESSION TITLE: Photoreceptors and the OPL

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: U. Bocchero, L. Levy, J. Pahlberg, NEI, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Ulisse Bocchero: Commercial Relationship: Code N (No Commercial Relationship) | Lior Levy: Commercial Relationship: Code N (No Commercial Relationship) | Johan Pahlberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The intrinsic noise of the sensory transduction cascade sets fundamental limits for signal detection in sensory neurons. Indeed, the rod phototransduction cascade displays two forms of dark noise called discrete and continuous noise. Thediscrete noise is thought to originate from spontaneous activation of rhodopsin (Rh). Continuous noise has been proposed to be generated in the downstream signaling cascade. Both types of noise have been proposed to limit some aspects of single photon detection in rod photoreceptors. However, it is not clear which form of noise ultimately limits visual perception.

Methods: In our study, we used several mouse strains that express altered concentration of key phototransduction proteins, namely Rh, Transducin (Tr) and phosphodiesterase (PDE6), or a modulatory protein of PDE activity (GARP2 KO mice). We recorded discrete and continuous noise in rods using the single cell patch clamp technique. In the same mice, we analyzed how the synaptic transmission between rods and rod bipolar cells (RBCs) is altered by these manipulations, using the perforated patch technique.

Results:

Rh heterozygous rods indeed express half the amount of Rh, resulting in a reduction of the discrete noise events by half. No alterations of continuous noise were detected in these rods, or in Tr heterozygous mice. On the other hand, halving PDE concentration leads to a significant change in continuous noise. Interestingly, our preliminary results suggest that GARP2 KO mice show a reduction in dark noise, demonstrating the importance of controlling the activity of spontaneous PDE activity for proper single photon detection.

Conclusions: Our results suggest that spontaneous thermal activation of rhodopsin indeed is the source of the discrete noise. Moreover, we demonstrate that continuous noise originates in spontaneous activation of PDE and the cGMP turnover rate. Our mouse models will serve as a critical tool to determine the limiting noise that sets detection threshold in the retina near the absolute limits for vision, currently under investigation.

ABSTRACT BODY:

Purpose: Prior studies have shown that patients with diabetic retinopathy, particularly proliferative diabetic retinopathy, have high rates of becoming lost-to-follow-up (LTFU), as well as worse clinical outcomes after inadvertent treatment lapses. The purpose of this study was to create a predictive model for risk of becoming LTFU after a clinical encounter for diabetic retinopathy using electronic health record (EHR) data.

Methods: EHR data were extracted for all diabetic retinopathy clinical encounters at an academic medical center in Durham, NC from January 1, 2014 to March 15, 2020. Specifically, data on healthcare utilization, demographic factors, and ophthalmic clinical parameters were collected. Information on imaging and therapeutic procedures (i.e. anti-VEGF injection or panretinal photocoagulation) was included. LTFU was determined by diabetic retinopathy stage based on ICD coding and the recommended follow up interval in the AAO Preferred Practice Pattern for diabetic retinopathy. LASSO and random forest models were constructed using LTFU as the outcome using (1) only data available prior to the clinical encounter and (2) data collected during the ophthalmic clinical encounter.

Results: Data for 25,576 clinical encounters for 7,948 patients were extracted. Of these, 12,971 encounters (50.7%) were for proliferative diabetic retinopathy. LASSO and random forest models were created using pre-encounter data, including healthcare utilization and demographic data. Both models had an area under the curve (AUC) of 0.72. A LASSO model utilizing these parameters, as well as ophthalmic factors, had an AUC of 0.74 while the random forest model had an AUC of 0.75. Additional analyses were performed to construct a LASSO model for LTFU by race. While there was some variation, the AUC for all models for racial subgroups were between 0.70 and 0.80.

Conclusions: High performing EHR models for health services utilization typically have an AUC of 0.70 to 0.80. This EHR-based study using structured data fields presents a high performing predictive model to understand risk of becoming lost-to-follow-up for diabetic retinopathy patients. Models involving ophthalmic clinical factors perform slightly better than models considering healthcare utilization and demographic data alone. This study provides further opportunities for direct implementation into clinical care to understand LTFU risk in real time.

ABSTRACT BODY:

Purpose: To determine the effect of hyperglicemia on the production of N-truncated beta amyloid peptides in the anterior lens capsule from cataracts of diabetic patients

Methods: Informed consent was obtained from all patients. Samples were collected from 40 age-related cortical cataract and diabetic patients over 50 years of age with LOCS II score of nuclear color ≥4 along with 40 age-related cortical cataracts from nondiabetic patients subjects after phacoemulsification surgeries. Lens capsules were processed for immunofluorescence, western blot, immunoprecipitation and ELISA to determine the localization and concentration of Aβ-42, Aβ3-42, and Aβ11-42 peptides in DP and compare them with control cases (non diabetic patients).

Results: The results show the intracellular presence of Aβ-42, Aβ3 -42and Aβ11-42 peptides in cells of the anterior lens capsule, prinncipally from cataracts from DP. Surprisingly, there is a major accumulation and production of Aβ3-42 in capsule lens cells from ARC from DP. These peptides accumulates in the external membrane probably causing mitochondrial damage and it could be related to the development and progression of ARC. Western blot and ELISA assays also shows the presence of Aβ-42, Aβ3 -42and Aβ11-42 peptides. Aβ3 -42and Aβ11-42 peptides concentratioon values demonstrate that there is a statistically differences between ND and DP ($p= 0.017$). Additionally, we detected an increase in the production of pro-inflammatory citokines in cells from ARC from DP.

Conclusions: We show for first time the presence of Aβ42, Aβ3-42, Aβ11-42 peptides in mitochondria and the activation of inflammatory cytokines from tissues affected by the development of ARC from diabetic patients. These AD markers are present in the cells of the anterior lens capsule from ARC of diabetic patients. These markers could be related to the development and progression of ARC an it could be used as an early marker of cognitive imparmeint in aging.

ABSTRACT BODY:

Purpose: Worldwide 15 million premature infants are born each year, one in ten will develop ROP and Latin America has 40% of cases of childhood blindness. Therefore, epidemiological knowledge is important to implement prevention and screening programs. The purpose of this study is to evaluate the epidemiological characteristics in patients with ROP in a referral ophthalmology center, from January 2016 to December 2021.

Methods: A retrospective, descriptive and observational study was done according to the Screening Guidelines for ROP in Mexico, so patients with a history of gestational age inferior to 34 weeks and/or birth weight lower than 1750g were included; data was collected from an electronic file of The Mexican Institute of Ophthalmology I.A.P. (IMO) in Queretaro, Mexico. The study included infants who received ophthalmologic screening for ROP between January 1, 2016, to December 31, 2021.

Gestational age, birth weight, perinatal history, supplementary oxygen use, maternal history, and staging of ROP were analyzed. incomplete medical records were excluded.

Statistical analysis was performed using the Pearson Statistical Correlation in SPSS IBM 24.0 for windows 10.

Results: 715 patients with a mean gestational age of 35.70 weeks (min 30 max 65, SD 3.80) were included, and mean birth weight of 1595.03gr (min 740 max 2195, SD 330.76), the ROP patients have mature retina in 16.1% and it was immature in 83.9%. The most prevalent ROP stage was 1 with 56.2%, followed by stage 2 with 29.6%, stage 3 with 11.6%, there was only 1.3% for both stage 4A and 4B, and there were no cases in stage 5. The most common zone was 2A in 42.8%. The Pearson test results was a positive correlation in all categories compared with ROP Stage and a negative correlation in all categories compared with the ROP zone.

Conclusions: Currently, the population studied in our institute is in the third wave of ROP, as in India, since we are finding premature babies with higher weight and gestational age and with more retinopathy of prematurity, contrary to what happened in our previous study. It was also found that the lower the gestational age, the more immature retina. It is thought that there are not so advanced stages due to the timely screening we are carrying out and those with a higher stage are because they are referred from other hospitals or private pediatricians. We conclude that screening allows early control and treatment for our population.

ABSTRACT BODY:

Purpose: To compare the rate of visual field (VF) loss (mean deviation dB/year) before and after POAG diagnosis
Methods: 282 participants developed POAG in OHTS 1 and 2. VF tests (30-2 and 24-2 test strategies) HFA were completed every 6 months for 12 years in OHTS 1 and 2 and at 20-year visit in OHTS 3. Diagnosis of POAG required: 1. Reproducible optic disc deterioration and/or VF abnormality as determined by Reading Centers. 2. Attribution of change to POAG by a masked Endpoint Committee. Calculation of pre-POAG slope required at least 3 VF's over 3 years prior to POAG. Calculation of post-POAG slope required at least 3 VF's over 3 years after POAG. Slope coefficient (MD dB/year) was calculated for each eye separately using simple linear regression.
Results: 83% (1,354 of 1,636) of the participants did not develop POAG in either eye in OHTS 1 or 2. The slope of MD from baseline to last f/up visit was -0.07 dB/yr among these participants. 360 eyes of 282 participants developed POAG in OHTS 1 or 2. The mean (SD) age of participants at the time of POAG diagnosis was 66 (10 SD) years, median (range) time to POAG from baseline was 7.0 (0.6 to 14) years and median follow-up after the diagnosis of POAG was 8 years.

66% of 179 participants developed unilateral VF POAG and 34% were bilateral. Mean post-POAG slopes were markedly greater than pre-POAG slopes (Table 1). Mean post-POAG slopes were linear through 20 years of f/up. 41% of the eyes that developed VF POAG progressed at a rate of -0.5 dB/year or more and 23% of these eyes progressed at a rate of -1.0 dB/year or more.
Conclusions: Among eyes that developed POAG, the rate of change in MD dB/year increased substantially after the diagnosis of POAG. The slope of VF loss after the diagnosis of POAG was linear through 20 years.

ABSTRACT BODY:

Purpose: To describe a single surgeon's experience with dual blade goniotomy in addition to usual fenestrating slits to enhance early IOP lowering in non-valved aqueous shunt (tube) surgery in eyes with primary open angle glaucoma (POAG).

Methods: A retrospective chart review was conducted of all consecutive non-valved tubes with usual fenestrating slits with additional dual blade goniotomy performed by a single surgeon (MQ) between 10/1/2019-10/1/2021 in eyes with POAG. Eyes with prior traditional glaucoma surgery or cyclophotocoagulation were excluded. Three patients were excluded due to missing POW4 data. All cases were Baerveldt-350s and stented with a 3-0 Prolene ripcord, ligated with 7-0 Polysorb, and fenestrated 3 times with a spatulated SE-160-8 needle. This analysis focuses on the early post-operative period between POD1 and POW6 (when the ligature dissolves).

Results: Eleven eyes from 11 patients were included; mean age was 69.2 years, 5/11 were female, 11/11 were African American, 11/11 had severe stage POAG, 6/11 had prior SLT, and 2/11 had prior vitrectomy. Concurrent cataract surgery was performed in 7/11 eyes, the other 4/11 were already pseudophakic. Mean pre-op IOP was 22.2 on 3.9 meds. Mean IOP on POD1 was 17.1 mmHg, mean IOP on POW1 was 16.5 mmHg on 4.0 meds, mean IOP on POW4 was 15.5 mmHg on 4.0 meds. After the ligature dissolved at POW6, mean IOP was 11.2 mmHg on 4.0 meds. Two eyes had hyphemas <=1.0mm at POD1 which resolved by POW1, and there were no reflux hyphemas at POW6 when the ligature dissolved. One eye had IOP spike >30mmHg at POD1 and a different eye had IOP spike at POW1; there were no IOP spikes at POW4 or POW6. No eyes had shallow AC or other hypotony associated complications at any time point.

Conclusions: Excessively large fenestrating slits and/or early ripcord removal in non-valved tubes may carry a risk of hypotony associated complications. We demonstrate our novel surgical strategy of performing a goniotomy at the time of non-valved tubes, in addition to usual small fenestrations, to enhance IOP-lowering in the early postoperative period (POD1-POW6) before the ligature dissolves. The additional goniotomy enhances IOP lowering without risk of hypotony-associated complications, since the additional aqueous outflow from the goniotomy is via the physiologic outflow pathway.

ABSTRACT BODY:

Purpose: Vsx2 is an important and highly conserved transcription factor during retinal development process and its mutations lead to microphthalmia in humans and mice. During early development, Vsx2 is expressed in retinal progenitor cells (RPCs) while later it is exclusively expressed in bipolar neurons and at low levels in Müller glia. How is this precise temporal and spatial pattern of expression achieved during retinal development remains poorly understood. We hypothesized that enhancers should playing an important role in achieving the precise expression of Vsx2.

Methods: Enhancers were tested for their ability to activate expression of reporter genes in developing mouse retinas, using electroporation into retinal explants. We deleted one promising enhancer in mouse using CRISPR/CAS9 technology to examine the functionality of it. Retinas at E14.5 and adult stages were then collected for immunostaining or RNA-seq study.

Results: We identified Vsx2 elements that drive robust reporter expression within the developing retina. Genetic deletion of a Vsx2 enhancer element leads to microphthalmia, recapitulating retinal defects observed in Vsx2-null mutant mice. However, different from Vsx2-null mutant mice, these knock out mice still have bipolar cells. RNA-seq results from E14.5 samples showed that cell proliferation process was affected in the knock-out mice. And these results were further confirmed by immunostaining of EdU and Ki67.

Conclusions: Taken together, our results revealed a cell specific cis-regulatory element which is responsible for the expression of Vsx2 and proliferation of retinal progenitor cells in retinal development. Thus, providing insights onto gene regulatory networks that govern Vsx2 expression during retinal development.

ABSTRACT BODY:

Purpose: To investigate whether ETDRS DRSS and lesion measurements evaluated in a reading center setting on 4-widefield (WF) and different ultra-widefield (UWF) color fundus photography (CF) images differ from the current gold standard of 7-field CF images.

Methods: Patients with all stages of DR were imaged by an experienced photographer in randomized order according to standardized protocols of the Vienna Reading Center (VRC) with 7-field and 4-WF imaging (Zeiss FF450, mono+stereo) and UWF imaging (Optos California, Zeiss Clarus 700 2-WF protocol and UWF protocol). 6 retina specialists trained for ETDRS DRSS grading at the VRC evaluated the images (with a 7-field mask on each image) in random order. In addition, a different experienced CF grader measured distances of two landmarks seen on images of all modalities of each patient. All final scores were grouped into no/questionable (1), mild (2), moderate (3), severe (4) and proliferative (5) DR (DRSS-G). A logistic regression model with the DRSS-G as the dependent and the camera as the explanatory variable was fitted to investigate whether the grouped score differed from the gold standard and a linear mixed model was calculated to compare measurements.

Results: DRSS-G were distributed as follows: 23%(1); 6%(2); 26%(3); 31%(4); 10%(5). In the logistic regression model, no significant differences between the gold standard and other CF images for the DRSS-G were detected. Landmark distances were 1500-3000µm in size. Statistically significant differences between measurements in the 7-field CF images could be found for different subfields of each UWF camera, but no significant differences were found for 4-WF CF images. The delta of these differences was 5.4-14.5%, lowest in the macula (5.4-5.9%), highest in the superior nasal subfield (12.1-14.5%).

Conclusions: For DRSS-G grading the compared camera models can be used interchangeably in multicenter trials. Landmark measurements of 7-field and 4-WF images are fully comparable, whereas measurements on UWF images must be set into context with the intergrader variability of each landmark. However, it is not recommended to use different camera models for landmark measurements within one patient. Within a multicenter clinical trial using different CF models for different patients, differences may not be clinically relevant in any of the subfields.

ABSTRACT BODY:

Purpose: Teleretinal screening for diabetic retinopathy has been proven to increase compliance with annual screening. However, appropriate follow-up is needed in patients with abnormal screens in order to ensure treatment of vision-threatening diabetic eye disease and preservation of vision. Few studies have identified patient-specific barriers to follow-up after abnormal screening. This study aims to identify barriers to follow-up beginning at the time of the abnormal screen result through completion of the follow-up visit.

Methods: 184 patients underwent teleretinal screening for diabetic retinopathy during a nine-month period between 2019 and 2020 at a single primary care site at The Ohio State University Wexner Medical Center. These charts were retrospectively reviewed to determine whether a referral to ophthalmology was placed by the ordering physician, an ophthalmology visit was scheduled after referral to ophthalmology was placed, and if the visit was completed for those with ophthalmology visits scheduled.

Results: Of the 184 patients who underwent screening, 80 patients had abnormal screens with recommendations to refer to ophthalmology. Abnormal screens included diabetic retinopathy, as well as other pathology requiring follow-up including retinal tear, choroidal nevus, glaucoma suspect, etc. Of these 80 patients, 60 were referred to ophthalmology. 45 of 60 (75%) patients scheduled appointments. Factors identified as barriers in scheduling appointments include inability to successfully contact patient and patient declining to schedule when contacted. Of the 45 who scheduled appointments, 23 appointments were completed. 17 patients cancelled and 5 patients failed to show for their scheduled appointments.

Conclusions: Overall completion rate of follow-up visit after abnormal teleretinal screen in this study was 29%. While patient factors including lack of clarity in process following screening and cost have been previously identified as barriers to follow-up after teleretinal screening, other factors that impact follow-up include placement of referrals by the ordering physicians, ability to contact patients to schedule appointments, and patients declining to schedule appointments. Further research is necessary to elucidate barriers in placement of referrals, as well as ability to contact patients and successfully schedule appointments after abnormal teleretinal screen.

Thomas Brown: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During eye formation, cells and tissues undergo dramatic movements to generate the precise 3-dimensional structure that is crucial for visual function. We lack a comprehensive understanding of the dynamic cell and tissue interactions governing eye morphogenesis, which have implications for structural malformations underlying vision impairment disorders. To uncover new genetic loci and processes shaping the eye, we carried out a haploid forward genetic screen in zebrafish for eye morphogenesis mutants.

Methods: A zebrafish haploid forward genetic screen was carried out in which the shutdown corner (sco) mutant was isolated. 4D imaging datasets were acquired via confocal microscopy, and cell tracking performed using our LongTracker software. Antibody staining was used to visualize extracellular matrix (ECM). CRISPR mutagenesis was used to screen genes in the deletion interval for their ability to phenocopy the sco phenotype.

Results: In a haploid screen, we isolated shutdown corner (sco), which exhibits an intriguing novel eye morphogenesis defect: the retina and lens make initial contact normally, but then fail to detach, abolishing the space between the retina and lens. Contact between the prospective retina and lens is necessary for reciprocal signaling and coordinated invagination, but how these tissues detach is unknown. The retina-lens space is where the hyaloid vasculature forms: in sco, the hyaloid vasculature exhibits delayed abnormal development. 4D cell tracking of sco mutants reveals that neighboring cells in the retina and lens move normally. ECM molecule deposition (e.g. laminin and hyaluronic acid binding protein) is altered, however, and preliminary transmission election microscopy suggests aberrant features at the retina-lens interface. Subsequent retinal development is impaired. RNAseq analysis revealed a 10 Mb deletion (~100 genes) in sco. Using CRISPR screening in the deletion interval, we identified the causative gene: the chondroitin sulfate proteoglycan versican a (vcana).

Conclusions: The shutdown corner (sco) mutant uncovers a previously unappreciated, genetically regulated step of eye morphogenesis: retina-lens detachment, which is necessary for proper retina and hyaloid vasculature development. The chondroitin sulfate proteoglycan versican is the causative gene, and we are now working to determine the molecular mechanism by which versican facilitates retina-lens detachment.

ABSTRACT BODY:

Purpose: To study the nature of crowdfunding campaigns for common ophthalmologic procedures.

Methods: Out study is a cross sectional, retrospective study of campaigns on GoFundMe.com from January 1st, 2021 to July 31st, 2021. We included all domestic and international campaigns referring to cataract and intraocular lens placement or LASIK procedures, excluding those with non-ophthalmologic conditions or campaigns for multiple conditions. Descriptive analysis of campaigns including condition, country of origin of patient, total and median value raised, total and median value sought, age of the patient, funding goal met, and insurance status when possible.

Results: 137 campaigns were identified, 67.9% (93/137) were for cataract and 32.1% (44/137) were for LASIK. 13.1% (18/137) of campaigns were international. 7.3% (10/137) campaigns were successful at reaching their funding goal. Of the successful campaigns, 70.0% (7/10) were for cataract and 30.0% (3/10) were for LASIK. Total value raised (in USD) was $131,763, where $106,593 was for cataract and $25,170 was for LASIK. The median value sought overall was $5,000, where the median sought for cataract procedures was $5,000 and the median for LASIK was $4,000. The median value raised was $395. 5.8% (8/137) of campaigns mentioned minors. 12.5% (1/8) of campaigns for children or minors were successful at reaching their funding goal, compared to 7.0% (9/129) adult campaigns. The total funds raised for children or minors was $9,224 with a goal of $41,050. The total funds raised for adults was $122,539 out of a goal of $775,617. 14.6% (20/137) campaigns mentioned insurance coverage, of which 85% (17/20) were for cataract and 15.0% (3/20) were for LASIK. Premium lenses (toric, multifocal, etc) were mentioned in 1.1% of campaigns (1/93) as being cost prohibitive.

Conclusions: Crowdfunding is ineffective as a means for patients to raise funds for cataract surgery and LASIK. The broad range of financial requests for cataract surgery, an insurance covered procedure, indicates a large patient knowledge gap in cost for procedures.

ABSTRACT BODY:

Purpose: Epidermolysis bullosa (EB) is a disease characterized by blistering, scarring, recurrent corneal erosions, and refractory corneal ulcers. Additionally, it presents with early-onset pain and irritation, which is not a usual presentation of disease with severe corneal nerve loss, such as neurotrophic keratopathy. Our aim is to illustrate severe corneal nerve loss using quantitative analysis by in vivo confocal microscopy (IVCM) images in EB patients

Methods: Case reports of five EB patients (ten eyes) who presented with ocular and systemic features of the disease, as confirmed by systemic evaluation and ocular examination. Records of best-corrected visual acuity (BCVA), ocular and periocular involvement, and comprehensive slit-lamp biomicroscopic evaluation, were summarized alongside IVCM findings

Results: The mean age of the patients were 13±3.08 (range 11-18) years. The mean total, main and branch corneal nerve density were 2,201.47 ±3,015.26 (range 0-8,646.64) $\mu m/mm^2$, 965.39 ±1,388.38 (range 0-3,104.53) $\mu m/mm^2$, and 1,236.09±1,893.41(range 0-5,542.11) $\mu m/mm^2$ respectively. This degree of corneal nerve loss is consistent with repeated abrasions and ulcers, which is both the primary factor in EB and a risk factor for neurotrophic keratopathy.

Conclusions: Epidermolysis bullosa is a painful and vision-threatening condition, which causes a significant decline in both quantity and density of corneal nerves. The repeated cycle of abrasion and scarring could play a role in progressive corneal nerve loss, as seen in early-onset EB, but may also be part of the pathogenesis of the disease..

ABSTRACT BODY:

Purpose: The aim of the study was to analyse the reliability of an offline artificial intelligence (AI) algorithm for community screening of diabetic retinopathy.

Methods: A total of 1378 patients with diabetes visiting public dispensaries under the administration of the Municipal Corporation of Greater Mumbai between August 2018 and September 2019 were enrolled for the study. Fundus images were captured by non-specialist operators using a smartphone-based camera covering the posterior pole, including the disc and macula, and the nasal and temporal fields. The offline AI algorithm on the smartphone marked the images as referable diabetic retinopathy (RDR) or non-RDR, which were then compared against the grading by two vitreoretinal surgeons to derive upon the sensitivity and specificity of the algorithm.

Results: Out of 1378 patients, gradable fundus images were obtained and analysed for 1294 patients. The sensitivity and specificity of diagnosing RDR were 100% (95% CI: 94.72-100.00%) and 89.55% (95% CI: 87.76-91.16%), respectively; the same values for any diabetic retinopathy (DR) were 89.13% (95% CI: 82.71-93.79%) and 94.43% (95% CI: 91.89-94.74%), respectively, with no false-negative results.

Conclusions: CONCLUSION

The Innovation –

Use of smartphone to take good quality fundus photographs

Portable, Sustainable and cost effective equipment for screening a large population.

Training unskilled workers to make them semi skilled and generating employment among the uneducated youth of India, preventing them from being a burden on society.

Generating semi skilled manpower to screen diabetics in villages. There are 6,64,369 villages in India – screening the population of these villages can be made easy with this model.

Early prevention of diabetic blindness – Screening and early detection of RDR (Referrable DR) by offline AI model can prevent diabetic blindness especially in young or undiagnosed diabetics, who may be the sole breadwinners in the family.

Sustainable model which does not require electricity or internet connectivity to work – best for rural areas.

Equipment can be transported on motorbikes and two wheelers easily.

The robustness of the offline AI algorithm was established in this study making it a reliable tool for community-based DR screening.

TITLE: Gut-microglia communication mediates glaucoma neurodegeneration
SESSION TITLE: Neurodegeneration
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: Y. Tang, MEEI, Harvard Medical School, Boston, Massachusetts, UNITED STATES|
Commercial Relationships Disclosure: Yizhen Tang: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Glaucoma neurodegeneration is reported to be associated with microbiota related retinal immune response. While how microbiota regulate the retinal immune response is still unclear.
Methods: Germ-free (GF) mice, specific pathogen free (SPF) mice and microbead-induced glaucoma mouse models were used to study the changes of retinal immune responses following elevated intraocular pressure. Moreover, primary microglia were isolated and stimulated by Lipopolysaccharide (LPS) for 24 h in culture. The cytokine arrays and RNA-seq analysis were performed to characterize the inflammatory responses and gene expression changes of microglia derived from GF and SPF mice.
Results: Retinal microglia of GF mice exhibited much reduced inflammatory responses and neurodegeneration under continuous elevation of intraocular pressure compared to those from SPF mice. LPS-stimulated primary microglia isolated from GF mice also displayed different gene expression profile, showing enriched angiogenesis, cell morphogenesis, and ameboidal-type cell migration-related genes by KEGG terms, when compared with those taken from SPF mice.
Conclusions: These results support that microbiota effect on retinal microglia and glaucomatous neurodegeneration by affecting retinal immune responses. This study provided novel insights and potential therapeutic targets for glaucoma.

ABSTRACT BODY:

Purpose: The predominant descriptive features of fundus images are the retinal vessels. The performance of a registration algorithm when applied to the fundus angiography images is often not optimal due to the poor contrast of retinal vessels in the early stages of angiography. In this research, we propose a weighted foreground-background registration (FBR) method to improve the performance.

Methods: The workflow of the proposed method is shown in Figure 1. Retinal vessels images (RVI) are detected using first-order derivative of the Gaussian filter in image pairs. Registration is applied in two steps. 1) Coarse registration: Harris corner detection is applied to RVI pairs followed by non-maximal suppression. Feature point matching is done between the RVI pairs and the transformation is applied to form a coarse registered image. 2) Fine registration: Retinal background image (RBI) is computed for the coarse registered image pairs by eliminating the retinal vessels and applying contrast limited adaptive histogram equalization (CLAHE) for simultaneous noise reduction and contrast enhancement. Feature point matching is done between the RBI pairs and the transformation is applied to form a fine registered image.

Fluorescein angiography image sequences from 22 eyes (5 healthy and 17 subjects with various retinal pathologies) were acquired using CLARUS^{TM} 700 (ZEISS, Dublin, CA). Three image pairs from each of the eyes were randomly selected (1 image pair each from early, mid, and late phases) and six landmarks were labeled for each pair of the images [1]. The angular distance between the landmarks in the registered images should be minimal for ideal registration. The mean angular distance (MAD) with and without FBR was calculated for the quantitative evaluation.

Results: Table 1 shows the MAD for image pairs from different angiography phases. With FBR, the performance of the registration is improved by 9.5% in early phase and 7.1% in late phase. In the mid phase, the performance doesn’t show any improvement with FBR.

Conclusions: The proposed FBR algorithm may improve the registration in early and late phase angiography images by augmenting the feature point matching of retinal vessels with histogram equalized background information.

ABSTRACT BODY:

Purpose: We aim to demonstrate the use of a novel atlas-based segmentation method for orbital soft tissues on normal and thyroid eye disease (TED) patients, and to characterize differences between normal and TED orbits using this method.

Methods: A novel consensus orbital soft tissue atlas was created by iteratively aligning 32 normal individual orbit CT scans with a variety of nonlinear registration protocols and then manually refined. The atlas was then used to identify soft tissue components of normal and TED orbits using a nonlinear registration process. Manual segmentation was used to assess accuracy. T-test was used to compare the two cohorts for each extraocular muscle and orbital fat compartment volumes, as well as to compare the ratio of fat to EOM volume for TED and normal control patients.

Results: Accuracy as determined by the Jaccard index (Intersection over Union, IoU) varied between 0.705 and 0.918 while the mean Dice coefficient ranged from 0.801 to 0.952. Orbit volumes based on 32 normal orbit CT scans and 37 TED orbit scans are summarized in Table 1.

TED orbits demonstrated significantly higher fat ($p = 0.00013$) and total EOM volume ($p = 0.00021$) compared to normal orbits. The ratio of fat to EOM volume was calculated for TED and normal control patients, and the distribution plotted on Figure 1. T-test was used to compare the two cohorts. Of 32 normal orbits compared to 63 TED orbits, the fat to EOM ratio measured 3.37 and 3.36, respectively ($p = 0.82$).

Conclusions: This automated atlas-based process produces accurate segmentation of orbital soft tissue compartments in normal and TED patients. This is the first fully automated segmentation of orbital soft tissue components, allowing for rapid determination of specific soft tissue compartment volume and density on CT, which has many potential clinical and research applications.

There does not seem to be a bimodal distribution of fat to EOM ratio, in contrast to previous publications which have suggested that there are subtypes of TED with primarily fat hypertrophy or primarily muscle hypertrophy. While there may be outliers on either end of the spectrum, the majority of TED patients in our cohort have a similar degree of fat and muscle volume expansion, and a similar ratio compared to normal controls.

TITLE: Comparison of delay in diagnosis of congenital cataracts between ethnic groups

SESSION TITLE: Pediatric Ophthalmology Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Puente, Jr., T. Lien, H.V. Neves da Silva, University of Colorado Denver School of Medicine, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Michael Puente, Jr.: Commercial Relationship: Code N (No Commercial Relationship) | Tiffany Lien: Commercial Relationship: Code N (No Commercial Relationship) | Helio Neves da Silva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Congenital cataracts should be removed within the first 6-10 weeks of life to reduce the risk of permanent visual impairment from deprivation amblyopia. However, congenital cataracts are often not diagnosed until a child is months or even years old. Given that racial and ethnic healthcare disparities are known throughout medicine and ophthalmology, we sought to determine whether there was a significant difference in the timeliness of diagnosis of congenital cataracts between ethnic groups at our institution.

Methods: We retrospectively reviewed records of all patients who underwent cataract surgery by a pediatric ophthalmologist at Children's Hospital Colorado from May 2009 to April 2020. We identified children whose cataracts were considered congenital by the diagnosing ophthalmologist and recorded the age at which they were first evaluated by a pediatric ophthalmologist. Using racial and ethnic information provided by each child's family in their medical record, we categorized children into the two categories of non-Hispanic White (NHW) and Racial/Ethnic Minority (REM). We then performed a two-tailed Mann-Whitney U Test to compare the age of diagnosis between the two groups.

Results: A total of 328 cataracts were extracted from 223 children during the study period, with 94 children having been diagnosed with congenital cataracts. Of those 94 children, 43 were non-Hispanic white, 48 were from other racial/ethnic groups, and 3 were of unknown race/ethnicity. The NHW children had a median age at diagnosis of 90 days and a mean age of 583 days, while the REM children had a median age at diagnosis of 159 days and a mean age of 709 days. This difference was not found to be statistically significant by a two-tailed Mann-Whitney U Test (p-value 0.30772).

Conclusions: The majority of children in our study were not referred to a pediatric ophthalmologist until they were already older than the ideal age for cataract surgery, regardless of their race or ethnicity. There was no significant difference in this delay between non-Hispanic white children and children of other racial or ethnic backgrounds. Though our study was limited by its small sample size, it highlights the crucial need to investigate and address the underlying reasons for delayed diagnosis of congenital cataracts. Such efforts should consider disparities in access to healthcare for children from different racial and ethnic backgrounds.

ABSTRACT BODY:

Purpose: Age related macular degeneration (AMD) is a degenerative disease of the central retina and the leading cause of irreversible blindness worldwide. We previously reported that CCL26 (eotaxin-3), an inflammatory chemokine, is epigenetically regulated by histone deacetylase-1/2 (HDAC1/2) in human retinal pigment epithelium (hRPE). In this study, we evaluated the expression of CCL11/24/26 (eotaxins-1/2/3) in eyes with atrophic AMD compared to age-matched controls and examined epigenetic regulation of CCL26 in targeted knockout (KO) models of HDAC1/2.

Methods: CCL11/24/26 levels in RPE/choroid tissues of advanced dry AMD patients (n=5) and age-matched controls (n=5) were determined using qPCR and immunohistochemistry (IHC). Viability of hRPE cells (n=3) was evaluated after treatment with different doses of recombinant CCL26 (10, 100, and 1000 ng/ml) for 48h followed by SYTOX staining. RNA samples and cell lysates of HDAC1/2 KO hRPE models generated using short-interfering RNA (siRNA) and CRISPR/Cas9 based approaches were analyzed using qPCR and multiplex bead arrays. HDAC1/2 interaction with the CCL26 promoter was observed using chromatin immunoprecipitation assay. Statistical testing was done (p-value <0.05) using the Mann-Whitney U test.

Results: Posterior segment showed high expression of CCL26, followed by CCL24 and low levels of CCL11. CCL26 mRNA was significantly increased in RPE/choroid (~7-fold change) in atrophic AMD patients compared to controls. IHC in whole eye sections revealed moderate CCL26 expression in the ganglion cell layer (GCL), inner nuclear layer (INL), outer nuclear layer (ONL) in both control and atrophic AMD eyes. However, in atrophic AMD eyes, elevated CCL26 deposition localized to RPE/Bruch's membrane. Human RPE cells treated with CCL26 demonstrated dose-dependent cytotoxicity. HDAC1/2 KO models showed increased CCL26 expression compared to controls. ChIP assay revealed enhanced binding of HDAC1/2 to CCL26 promoter which was blocked by a pan-HDAC inhibitor, valproic acid.

Conclusions: CCL26 expression in RPE/choroid is significantly elevated in atrophic AMD eyes compared to controls and is epigenetically regulated by HDAC1/2. Our results suggest that CCL26 may play a crucial role in the RPE cell death process observed in atrophic AMD. Collectively, our data suggest that selective neutralization of CCL26 may be therapeutically effective in the treatment of atrophic AMD.

ABSTRACT BODY:

Purpose: Our previous studies have demonstrated the presence of anti-citrullinated protein autoantibodies (ACPA) in ocular surface washes from patients with autoimmune dry eye disease (DED). Moreover, autoimmune DED was responsive to treatment with pooled human immune globulin (pooled IgG) eye drops. The purpose of this study was to develop a plate reader-based in vitro assay to evaluate therapeutics targeting neutrophil activation and neutrophil extracellular traps formation (NETosis). Specifically, the efficacy of pooled IgG in preventing neutrophil activation and NETosis were assessed.

Methods: Primary human neutrophils (HemaCare) were maintained in phenol red-free RPMI1640 media supplemented with 10% fetal bovine serum. 1×10^5 neutrophils were seeded into black/ clear bottom 96-well plates (FIAv plates, Greiner Bio) and stained with 1 µM SYTOX green (S7020, Thermo Fisher Scientific), a fluorescent dye that is impermeant to live cells and has a high affinity to nucleic acid. Subsequently, cells were allowed to settle for 20 min and subsequently stimulated with either phorbol 12-myristate 13-acetate (PMA; 100 nM; 79346, Sigma-Aldrich), or anti-histone 4 R3 ACPA (H4R3 ACPA; 100 ng/mL; Abcam, #ab81797). Fluorescence of extracellular NET-bound SYTOX Green (excitation λ: 488 nm, emission λ: 510 nm) was measured every 30 min for a period of 72 h using a microplate reader (Cytation 5, Biotek Instruments) at 37°C. Dose-responses (0.001 – 4%) of pooled human IgG diluted in saline (Flebogamma) were tested for the ability to inhibit NETosis.

Results: H4R3 ACPA resulted in ~2-fold increased SYTOX Green fluorescence over a 72 h period indicating neutrophil activation and NETosis. The level of NETosis elicited by H4R3 ACPA was similar to activation by PMA. Pooled IgG resulted in a dose-dependent decrease in SYTOX Green fluorescence that could be fitted with a fourth parameter non-linear regression ($R^2 = 0.95$). 1% pooled IgG reduced SYTOX Green fluorescence to 115.4 ± 10.9% (mean ± S.D.) of control for H4R3 ACPA-induced NETosis and 99.6 ± 9.1 % (mean ± S.D.) for PMA-induced NETosis.

Conclusions: The plate reader-based SYTOX Green assay provides a standardized platform for testing NETosis-targeted therapeutics. Pooled IgG exert potent protection against ACPA-induced NETosis in vitro. Our findings confirm observations from our previous studies that have shown improvement of ocular surface pathology following Pooled IgG administration.

TITLE: Localized peripheral choroidal response to signed defocus with and without native aberration

SESSION TITLE: Myopia and refractive error development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Pusti, G. Yoon, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Dibyendu Pusti: Commercial Relationship: Code N (No Commercial Relationship) | Geunyoung Yoon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Unlike the defocus-dominated central retina, peripheral ocular optics are affected further by astigmatism and complex higher-order aberrations that cause apparent directional blur in an image formed on the retina. The peripheral choroidal response to defocus may differ from the fovea. Hence, we aim to evaluate peripheral choroidal response to short exposure of defocus signals with and without the presence of peripheral native aberrations.

Methods: The temporal 15° retina was exposed for 30 min with a video stimulus (±4° horizontal & ±3° vertical visual field), providing a wide range of time-varying spatial frequency and contrast without exposing the foveal region. The fellow eye was used to fixate at the eccentric fixation target. We used a custom-built adaptive optics (AO) visual simulator to induce pure defocus with and without correcting peripheral ocular aberrations. Four subjects with cycloplegia underwent four separate sessions: AO-controlled myopic defocus (AO-Myo), AO-controlled hyperopic defocus (AO-Hyp), myopic defocus without AO (NoAO-Myo), & hyperopic defocus without AO (NoAO-Hyp). The choroidal thickness (ChT) was measured using Heidelberg Spectralis OCT. ChT in the peripheral retina exposed to the defocus and at the fovea was captured at 0, 10, 20, & 30min exposure time points. The response is represented by the averaged ChT change from baseline measurement.

Results: All tested optical conditions showed a bi-directional ChT alteration at the peripheral exposed ocular region, in which myopic and hyperopic defocus caused choroidal thickening and thinning, respectively. On average, AO-controlled conditions showed more significant ChT change from the baseline (AO-Myo: 10.67±9.89μm, AO-Hyp: -9.77±6.58μm) compared to those without AO (NoAO-Myo: 5.53±6.88μm, NoAO-Hyp: -0.55±5.26μm). The highest ChT alteration was seen at 20min (7.53% thickening) & 30min (-6.97% thinning) under AO-Myo and AO-Hyp conditions respectively. The unexposed foveal region showed insignificant thickness alteration under all test conditions.

Conclusions: Peripheral complex blur signals due to astigmatism and higher-order aberrations reduced the choroidal response to both signs of defocus compared to the pure defocus exposure with AO. The choroidal response remains localized to the defocus exposed region.

ABSTRACT BODY:

Purpose: Transplanted healthy RPE cells may benefit AMD patients. We created allogenic RPE cells (OpRegen) using directed differentiation. Safety and tolerability of OpRegen is being evaluated in a Phase 1/2a clinical study in patients with dry AMD and geographic atrophy (GA) (NCT02286089). We report safety and imaging data from the primary endpoint for all patients (N=24).

Methods: Subretinal transplantation of 50-200k OpRegen cells in suspension were delivered to the worse vision eye via pars plana vitrectomy (PPV) and retinotomy (n=17) or via a suprachoroidal route (n=7). Short course, perioperative systemic immunosuppression was used. Endpoints include systemic/ocular safety and retinal structure/function.
Results: Patients in cohorts 1-3 (<20/200) have completed (4/12), entered long-term follow-up (F/U) (6/12; 3-5 yrs) or withdrawn (2/12). Cohort 4 patients (<20/64) continue in F/U (11/12; 1-3 yrs, 1 withdrawal). OpRegen has been well tolerated to date, with no unexpected adverse events (AEs). Using PPV, the most common ocular AEs were mild to moderate epiretinal membranes (ERM) (15/17; 88%); 3 (18%) severe ERM required surgical peeling. Two PPV-treated patients (2/17; 12%) developed retinal detachments, which were successfully treated. In patients treated via a suprachoroidal route, 3 mild AEs of CNV were reported; one successfully treated with a single anti-VEGF injection; 2 responsive to regular administration. Disease in cohorts 1-3 typically progressed as expected in advanced GA. However, in cohort 4 patients, improvement or maintenance of baseline visual acuity has been noted in 9/12 (75%) (-2 to +24 letters). Treatment effects, including alterations in drusen appearance, subretinal pigmentation and hyper-reflective areas, suggest persistence of transplanted OpRegen. Patients with atrophic areas extensively covered by the subretinal surgical bleb containing the cell suspension (4/12) have potential signs of outer retinal restoration and reduction in GA area based on OCT analyses of the periphery of the GA compared to baseline imaging.
Conclusions: Subretinal transplantation of OpRegen cells in dry AMD and GA patients appears well tolerated. Imaging findings suggest presence of transplanted cells in the subretinal space. Encouraging structural and clinical changes observed in some patients are being followed.

ABSTRACT BODY:

Purpose: To evaluate postoperative visual outcomes in patients treated with photoablative refractive surgery, including photorefractive keratectomy (PRK) and laser-assisted in situ keratomileusis (LASIK), at a teaching institution with trainee involvement in preoperative planning.

Methods: This is a retrospective chart review of patients (age 22 to 57) treated with photoablative refractive surgery, including PRK and LASIK, from 11/2/2018 to 3/29/2021 at Cook County Health. Preoperative evaluation, surgery, and postoperative visits were conducted for each patient. All cases with trainee involvement were supervised by an attending surgeon. Follow-up examinations were performed at 1 day, 1 week, 1 month, and 3 months or greater postoperatively. The primary outcome measure is final postoperative visual acuity at 3 months or greater.

Results: 147 eyes of 74 patients were evaluated. 89 eyes were treated with PRK and 58 eyes were treated with LASIK. Average preoperative spherical equivalent was -3.63D (range -8.75D to +5.50D). Final postoperative uncorrected visual acuity (UCVA) of 20/25 or better was seen in 90.48% of eyes (133 of 147 total eyes). UCVA of 20/25 or better was achieved in 93.18%, 89.47%, and 89.13% of eyes that were preoperatively evaluated by resident trainees (RES), cornea-refractive fellow trainees (FEL), and attending surgeons (ATT), respectively. When separated by type of procedure, eyes that were preoperatively evaluated by the RES group achieved UCVA of 20/25 or better in 93.94% and 90.91% in the PRK and LASIK groups, respectively. Five eyes required postoperative enhancements - 3 out of 44 from the RES group, 0 out of 57 from the FEL group, and 2 out of 46 from the ATT group. No patients had significant postoperative complications.

Conclusions: Residents and fellows can safely and effectively be involved in preoperative planning for photoablative refractive surgery with excellent outcomes, comparable to that of attendings.

ABSTRACT BODY:

Purpose: Choroidal vascular changes occur with normal aging and may also be associated with retinal diseases such as age-related macular degeneration (AMD). Here, we evaluate choroidal thickness and vascularity in rhesus macaques across their adult lifespan, and in animals that exhibit soft drusen, to determine the potential role of the choroid in the pathogenesis of this nonhuman primate model of AMD.

Methods: We analyzed spectral domain-optical coherence tomography (SD-OCT) images of 234 eyes from 117 rhesus macaques (range 4 - 32 years of age). Sub-foveal choroidal thickness (CT) measurements were performed using the Heidelberg Explorer software, while choroidal vascularity was measured by binarization using Niblack's auto-local threshold to measure total choroidal area (TCA) and luminal area (LA), and to calculate stromal area (SA) and choroidal vascular index (CVI). Regression analyses were used to determine the relationship between CT and CVI with age, while Student's t-tests were used to detect differences in CT and CVI in the presence or absence of soft drusen.

Results: Sub-foveal CT decreases with age at 3.2 μm/year (R^2 = 0.481, P < 0.001), while CVI also decreases over time at 0.67% per year (R^2 = 0.275, P < 0.001). Eyes with soft drusen exhibited thicker choroid (171.5 μm ± 12.2 μm vs. 137.4 μm ± 12.2 μm, P < 0.001) and higher CVI (0.606 ± 0.041 vs. 0.459 ± 0.107, P < 0.001) than age-matched control animals. In eyes with drusen, neither CT or CVI appear to be associated with drusen number, size, or volume.

Conclusions: Changes in choroidal vascular architecture in rhesus macaques resemble choroidal changes in human aging, although the relationship with age-related soft drusen in these animals appears less clear when compared to AMD in humans. The relative contribution of the choroid to drusen pathogenesis in monkeys may be different from its role in human AMD.

ABSTRACT BODY:

Purpose: A critical, yet often-overlooked, step enabling efficient perception of light is the dephosphorylation of rhodopsin, mediated by protein phosphatase 2A (PP2A). PP2A deficiency has been reported to impair rhodopsin regeneration after phosphorylation by rhodopsin kinase (GRK1) and arrestin (Arr1), thereby delaying rod dark adaptation, although its effects on the viability of photoreceptors in the absence of GRK1 and Arr1 remain unclear. Here, we investigate the effects of PP2A deficiency in the absence of GRK1 or Arr1, both of which have been implicated in Oguchi disease, a form of night blindness.

Methods: We utilized a rod-specific mouse line lacking the predominant catalytic Cα-subunit of PP2A, which was crossed with $Grk1^{-/-}$ or $Arr1^{-/-}$ strains to obtain corresponding double knockout lines. To evaluate rod function, mice were dark adapted overnight for ex-vivo transretinal electroretinography (ERG). To assess rod photoreceptor viability, histological cross-sections of retina were stained with hematoxylin and eosin, and spider plots were generated by manual counting of photoreceptor nuclei in the outer nuclear layer at fixed distances from the optic nerve head.

Results: PP2A deficiency alone did not impair photoreceptor viability up to 12 months of age. Ex-vivo ERG revealed rod function in $Arr1^{-/-}$ mice was reduced by approximately 80% at 3 months, and this effect was exacerbated by an additional ~10% with concomitant PP2A deficiency. $Arr1^{-/-}$ mice exhibited mild retinal degeneration of approximately 10-15% relative to age-matched controls, and concomitant PP2A deficiency accelerated degeneration by an additional 10% at 6 months but not at 3 or 12 months of age. Histological and spider plot analyses in $Grk1^{-/-}$ mice revealed retinal degeneration of approximately 20% relative to age-matched controls at each time point, which was exacerbated up to an additional 10% with concomitant PP2A deficiency.

Conclusions: Our results demonstrate that deficiency of PP2A in the absence of Arr1 results in further suppression of rod responses. Moreover, while PP2A is not required for survival of rod photoreceptors, its deletion accelerates the degeneration induced by inefficient inactivation of rhodopsin in the absence of either GRK1 or Arr1. Further mechanistic studies will be required to delineate the pathways involving protein dephosphorylation by PP2A pertinent to retinal degenerative diseases causing blindness.

ABSTRACT BODY:

Purpose: Prior investigations demonstrated that iodothyronine deiodinase (Dio2) gene expression, the enzyme that converts thyroxine (T4) to triiodothyronine (T3), is decreased in the mouse retina during diabetes. As well, exogenous T3 supplementation of primary mouse retinal endothelial cells (mREC) in culture prevented high-glucose induced cell death. Yet, investigations of Dio2 function in mREC under high glucose conditions and the mechanism underlying thyroid hormone effects on the retinal microvasculature have not been studied.

Methods: T4 and T3 were simultaneously quantified by liquid chromatography-tandem mass spectrometry. mREC were cultured in physiologic (5 mM) or high glucose (30 mM). Cell lysates were analyzed after five days in culture for T4 and T3 concentrations. Endothelial nitric oxide synthase (eNOS) was detected in cell lysates by western blotting.

Results: When mREC were grown in the presence of high glucose, intracellular production of T3 decreased and T4 increased leading to a significantly increased T4/T3 ratio (P=0.007) when compared to cells grown in physiologic glucose. Supplementation of cells with T3, but not T4, increased T3 in mREC (P=0.007), consistent with suppressed Dio2 function under high glucose. Similarly, T3, but not T4, supplementation prevented the high glucose-induced rise in eNOS level (P=0.03).

Conclusions: Our study indicates that high glucose during diabetes may cause decreased intracellular T3 concentrations in retinal cells and that may lead to alterations in vascular tone and function, thereby contributing to the pathogenesis of diabetic retinopathy.

ABSTRACT BODY:

Purpose: Advanced retinoblastoma (Rb) tumors, if neglected can metastasize through the optic nerves to distant tissues and cause potent threat to vision and life. Since tumor metastasis by the epithelial to mesenchymal transition(EMT) also confers chemotherapy resistance, it is critical to understand this process in Rb tumors.

Methods: Transcriptomic analyses were performed on Rb tumor samples (n=9) & paediatric control retina (n=2) to identify EMT specific genes and microRNAs. Q-PCR & western blot was performed on WERI-Rb1 cells, under RB1 null & RB1 over expression, to assess EMT related miRNAs, genes & protein expression. Validation was performed by immunochemistry in tumor sections. Functions of miR-181a on tumor pathways were assessed using mimics and antagomirs.

Results: We found EMT and drug resistance genes to be differentially regulated in advanced and non-advanced Rb tumors compared to healthy pediatric controls ($P<0.05$, $FC>2$). EMT transcription factors ZEB1, SNAI2, Twist and drug resistance genes MDR1, CTSL were significantly upregulated in advanced tumors. ZEB1, SNAI2, MDR1 protein expression was higher in Rb tumor tissues. Reduced miR-181a observed in advanced Rb tumors inversely correlated with EMT and drug resistance genes. RB1 overexpression or miR-181a mimics significantly reduced cancer and EMT hallmarks. MiR-181a mimic enhanced chemosensitivity and reduced proliferative capacity of Rb null lines.

Conclusions: EMT and chemoresistance in advanced Rb tumors is characterised by higher expression of ZEB1, SNAI2, MDR1, CTSL, etc which mediate invasion and metastasis. MiR-181a transcriptionally controls the EMT program, reducing proliferation/invasion and enhances chemosensitivity, highlighting its potential for therapeutic applications.

ABSTRACT BODY:

Purpose: The early stage of age-related macular degeneration (AMD) is marked by loss of choriocapillaris and choroidal vessels, which leads to outer retinal hypoxia and subsequent pathological choroidal neovascularization (wet AMD). In health, endothelial cells (ECs) efficiently form new vessels to replace those lost to injury. Thus, here we investigated whether choroidal ECs from early AMD eyes lose their neovascularization potential and, if so, what potential mechanisms might underlie this impaired functional response.

Methods: Choroidal ECs were isolated from young normal (YN; 6 yrs old), old normal (ON; 20 yrs old), and old-drusen-laden (AMD; 19 yrs old) eyes of rhesus monkeys and plated at 20,000 cells/cm^2 on the surface of regular or type 2 (higher stiffness) Cultrex® basement membrane (10 mg/mL) in starvation medium composed of basal medium supplemented with 0.5% fetal bovine serum and antibiotics. Further, choroidal ECs isolated from the peripheral regions of AMD eyes were also compared with their corresponding macular counterparts. Images of capillary-like structures were obtained at 12h using a Zeiss Axio Observer 7 epifluorescence microscope, and total chord length per unit area was quantified using ImageJ.

Results: Our findings revealed that, of the three groups of choroidal ECs, those from AMD eyes exhibited the lowest neovascularization potential, which was 15% ($P<0.05$) or 48% ($P<0.05$) lower than their YN or age-matched ON counterparts, respectively. Notably, peripheral ECs from AMD eyes formed significantly (~1.6-fold; $P<0.05$) longer chord structures than their macular counterparts. Interestingly, the superior chord formation ability of YN ECs was substantially reduced on basement membrane of lower stiffness.

Conclusions: These studies show that choroidal ECs from early AMD eyes, and specifically those from the macula, exhibit poor neovascularization potential, which may explain their inability to replace the degenerating choroidal vessels in early AMD. Further, the observation that chord formation was impaired on softer basement membrane indicates a potential role of mechanotransduction in the observed differences in chord formation. Ongoing studies are aimed at further elucidating the molecular mechanisms underlying these spatial (macular vs peripheral) and temporal (young vs AMD) differences in neovascularization potential.

ABSTRACT BODY:

Purpose: Danon disease (DD) is a rare X-linked syndromic disorder resulting from mutations in the gene LAMP2 leading to dysfunctional autophagy. The exact contribution of lysosome-associated membrane protein 2 (LAMP2) deficiency to retinal degeneration in human DD remains unclear. We performed a phenotypic and functional characterization of human-induced pluripotent cell (hiPSC) derived RPE (hiPSC-RPE) cells possessing harboring a frameshift insertion in exon 2 of LAMP2 to better understand the pathogenesis of retinopathy in DD.

Methods: HiPSCs were generated using Sendai virus expression of Yamanaka factors in donor cells from an affected male patient with DD and unaffected control patient. The hiPSCs were differentiated to hiPSC-RPE using our in house protocol. We performed basic hiPSC-RPE characterization using immunostaining, electron microscopy (EM), rod outer segments (ROS) phagocytosis and autophagy analyses by performing LC3-II immunostaining and western blot as well as qPCR for LAMP2 isoforms

Results: Both DD and control hiPSC-RPE demonstrated expression of ZO-1, MITF, Bestrophin-1 and CRALBP RPE markers. Control hiPSC-RPE demonstrated a significantly greater expression of LAMP2A ($p<0.001$) and 2B ($p<0.001$) isoforms compared with 2C (Fig 1).

Phagocytosis of ROS in Danon hiPSC-RPE cells at 6 hours (21.4±18.9 ROS) was significantly greater ($p<0.05$) compared to control hiPSC-RPE cells (45.7±6.6 ROS) Western blot found no significant difference in LC3-II expression between the DD line and control line under normal conditions but did find a significant difference under conditions promoting autophagy including serum starvation ($p<0.05$) and under conditions blocking fusion of the autophagsomes and lysosome with the addition of hydroxychloroquine ($p<0.01$)(Fig 2).

Conclusions: Functional hiPSC-RPE were successfully differentiated from both a DD and control hiPSC line. Our findings suggest that there is a cell specific isoform expression signature in RPE. In addition, autophagic flux is impaired in DD hiPSC-RPE under stress, likely resulting in autophagosome accumulation and our finding of increased ROS preservation. These disease-relevant in vitro phenotypic markers will assist testing of approaches aimed at treating DD and other diseases in which LAMP2 deficiency is implicated. Further studies, with additional lines will be helpful to confirm these early findings.

ABSTRACT BODY:

Purpose: OCT angiography is a very important tool to detect macular neovascularization (MNV) but its value would be further strengthened by providing prognostic information. The aim of this study was to evaluate the outcomes of eyes with treatment naïve exudative age-related macular degeneration (AMD) based on baseline OCT angiography (OCT-A) morphology of type 1 MNV.

Methods: This was a retrospective study of treatment naïve AMD patients that developed exudative disease. MNV was classified as “distinct” or “indistinct/absent” in each patient at baseline with OCT-A and the kappa coefficient was calculated. Clinical and imaging data were reviewed at baseline and after 12 months of anti-VEGF therapy. Markers such as best-corrected visual acuity (BCVA), central macular thickness (CMT), subretinal fluid (SRF), intraretinal fluid (IRF), subretinal hyper-reflective material (SHRM), and retinal pigment epithelial (RPE) atrophy were evaluated using spectral-domain OCT.

Results: Twenty-six eyes of 26 patients were included in this study. Seven eyes displayed “distinct” MNV and 19 eyes displayed “indistinct” MNV. Kappa coefficient for classifying MNV among the graders was calculated to be 76% ($p<0.05$).

At baseline, there was no statistically significant difference in age, gender, and BCVA between both groups. The central macular thickness was lower in patients with distinct MNV (218 ± 68.7 vs 314.2 ± 48; p=0.002). RPE atrophy was more prevalent in the distinct MNV group (71.4% vs 15.8%; p=0.014). There was no statistically significant difference in percentage of subretinal fluid, intraretinal fluid, and SHRM between both groups at baseline.

One year after anti-VEGF therapy, signs of persistent exudation (SRF, IRF, or SHRM) were detected in 5 eyes (71.3%) in the distinct MNV group and 6 eyes (31.6%) in the indistinct MNV group (p=0.09). The number of anti-VEGF injections between both groups was not different (6.9± 3.1 vs 7.8± 3.1; p=0.69).

Conclusions: This study suggests that AMD patients with distinct type 1 MNV on OCT-A at baseline have greater central macular thinning and RPE atrophy compared to those with indistinct MNV. The distinct MNV group may be less responsive to anti-VEGF therapy after 1 year. Further studies with a larger sample size are mandatory to confirm these results.

ABSTRACT BODY:

Purpose: To describe the transient development and resolution of foveomacular vitelliform lesions in ABCA4 disease.

Methods: Patients were identified from a database of genetically confirmed biallelic ABCA4 disease (n=407). Longitudinal clinical data analysis included short-wavelength (SW-AF, 488-nm), and near-infrared (NIR-AF, 787-nm), spectral domain-optical coherence tomography (SD-OCT), OCT angiography (OCTA), electrooculogram and full-field electroretinogram (ffERG) recordings. Thickness of total retina, total receptor+ (TREC+), outer segment+ (OS+) and retinal pigment epithelium (RPE) layers were measured on horizontal SD-OCT scans and en face slabs of the inner segment ellipsoid (ISe) and RPE layers were derived from 97 raster scans.

Results: Three patients (mean age 24.3 years) presented with moderate bilateral central vision loss. The common feature of ABCA4 genotypes in all three cases was the p.(Gly1961Glu) allele. SD-OCT showed focal disruptions of the ISe at the fovea resulting in a concave displacement of the overlying outer nuclear layer, resembling optical gap lesions. Large intraretinal hyperreflective foci (IHF) directly above the lesions, corresponding to yellow deposits on fundoscopy, were observed in P2 and P3. At initial presentation, the base of the optical gap lesions in P1 were filled with a dense, egg yolk-like, autofluorescent fluid. Resolution of the vitelliform fluid occurred in 3 months after which similarly-appearing IHF were detected on SD-OCT. EOG recordings were within normal limits (Arden ratio >1.8) and no generalized dysfunction was detected on ffERG. OCTA of the choriocapillaris revealed subfoveal visibility of large choroidal vessels. Total retina and RPE thicknesses were within the 95% confidence interval of healthy control eyes; significant thinning of TREC+ was observed within and in a 1 mm perimeter around the lesion. This abnormality spatially corresponded to a halo of abnormal reflectance in the ISe layer (en face OCT) and a homogeneously bright elliptical region on NIR-AF. Vitelliform material and IHF were no longer visible in the retina after 2 years in all eyes.

Conclusions: Vitelliform lesions are rare, transient events associated with the p.(Gly1961Glu) allele of ABCA4. Early deterioration of the underlying choriocapillaris and formation of IHF may be contributing factors in the rapid resolution and rare incidence of vitelliform lesions in ABCA4 disease.

TITLE: Small incision sub-Tenon ab interno Xen implantation comparison to iStent, Trabeculectomy, and Tube shunt

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Baum, J. Bear, A. Roschke, B. Graham, J. Lee, Colorado Eye Institute, Colorado Springs, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Matthew Baum: Commercial Relationship: Code N (No Commercial Relationship) | Jacob Bear: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Roschke: Commercial Relationship: Code N (No Commercial Relationship) | Brianna Graham: Commercial Relationship: Code N (No Commercial Relationship) | James Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare small incision sub-Tenon ab interno Xen implantation with iStent, Trabeculectomy, and Ahmed tube shunt visual acuity (VA) changes and efficacy in treating primary open angle glaucoma.

Methods: Xen was implanted by a single surgeon using small incision sub-Tenon ab interno technique. 11 eyes from the start of 2020 until September 28th, 2021, were recorded. Each subject had their VA checked via computer Snellen chart, intraocular pressure (IOP) by applanation tonometer, silt lamp exam was performed to determine bleb avascularity, and glaucoma medications were checked at each visit. Data was taken from pre-implantation, 1-day post-implantation, and 6 months post-implantation. T-Test was performed for statistical significance. IStent, Ahmed tube shunt, and trabeculectomy data were compiled from previous studies

Results: The average age of subjects receiving Xen was 70 ± 10.79. Mean IOP at 6 months was 13.17 ± 1.64 ($p=0.003$, 12-17), median IOP was 12.5. Of these, 100% of subjects had IOP of 17 or below, 91% were 15 or below, and 55% of 12 or below. IStent mean IOP at 6 months was 15.8 ± 3.0 ($p<0.001$). Ahmed tube shunt had a mean IOP at 6 months of 12± 4.6 ($p<0.001$). Trabeculectomy IOP at 6 months was 13.4 ± 4.2 ($p<0.001$, 6-32) No eyes receiving Xen developed an avascular bleb due to the procedure.

Xen mean decrease of medications was 1.58 ± 1.31 at 6 months. IStent mean decrease in medications was 1 ± 0.8 ($p<0.001$). Ahmed tube shunt mean number of medications went from 2.97 ± 2.03 to 1.05 ± 1.15. Trabeculectomy medications went from 3.6 ± 0.9 (1-5) to 0.37 ± 0.9 (0-4).

Xen mean VA recovery time to return to normal was 1 week. IStent VA is neutral following surgery. Ahmed tube shunt worst VA occurred at 1 week postoperatively and mean VA returned to preoperative levels by 3 months. Trabeculectomy mean VA returned to preoperative levels in 88 days (6-720 days).

Conclusions: Xen had a lower IOP at 6 months than iStent with a similar decrease in medications, while mean visual acuity returned to baseline one week after. Xen had similar IOP at 6 months with Ahmed tube shunt and trabeculectomy, similar decrease in medications with Ahmed tube shunt, and faster return to preoperative VA. Since no eyes receiving Xen developed an avascular bleb, the tissue is still viable for possible additional procedures.

TITLE: Extensive genetic interactions between POAG loci add another layer of complexity in disease etiology

SESSION TITLE: Glaucoma Genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hirbo, E. Gamazon, N. Cox, Medicine, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Jibril Hirbo: Commercial Relationship: Code N (No Commercial Relationship) | Eric Gamazon: Commercial Relationship: Code N (No Commercial Relationship) | Nancy Cox: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is disparity in POAG prevalence, clinical presentations and outcomes across ancestries. Our previous Global Biobank Meta-analysis Initiative (GBMI) POAG meta-analysis, the largest and most diverse to date, from ~1.48 million individuals from six ancestries identified a total of 109 GWAS loci, 18 of which were novel. Ten of the GWAS loci are ancestry-specific. Additionally, we show heterogeneity in effects for 14 loci across ancestries and sexes. Considering genetic interactions may contribute to phenotypic complexity, we hypothesize that ancestry specific genetic interaction in POAG underlie observed disparity. In GBMI analysis we found evidence of a significant interaction between multi-ancestry SIX6 rs33912345 and causal variants in CDKN2B-AS1 locus, with concomitant effect on expression of CDKN2A, and CDKN2B.

Methods: We tested for genetic interactions in BioVU data for a subset of 65 lead SNPs that represent just over half of the overall loci identified in our GBMI study. We determined interaction using wtest in 49,034 European and 3573 African American BioVU patients. We further checked the effect of the loci i) that show interaction in both ancestries, and ii) with the highest number of significant pairwise interaction with other POAG loci in European patients, by checking the differences in the measured gene expressions of genes in a target locus in GTEx skeletal muscle tissues (N=716) between the haplotype background that has the reference and derived alleles. Statistical difference in expression was determined using ANOVA.

Results: We identified a total of 187 and 126 pairwise interactions in European and African American patients, respectively ($p<0.05$). These interactions are mainly due to 18 core loci with ≥5 pairwise interactions with other loci across the two ancestries: 6 common to both ancestry and 6 unique to each ancestry. Four core loci unique to African BioVu patients are African-specific. Chr3_rs62250629_CADM2 locus has pairwise interactions with 27 and 9 other loci in European and African American patients, respectively. The lead variant in the locus has significant trans effect on NEAT1 ($p= 0.006$) gene in chr11_ rs12789028 locus and interact with local GTEx eQTL to alter its expression pattern.

Conclusions: Our findings, if replicated (in other GBMI biobanks), point to genetic interactions as additional contributor to observed disparities in POAG.

ABSTRACT BODY:

Purpose: To examine the relationships between low birthweight (LBW), gestational age (GA) and subsequent neurodevelopmental outcomes in premature children who were screened for retinopathy of prematurity (ROP). Recent attention has been focused on potential impact on neurodevelopmental outcomes from ROP treatment, but there is a gap in knowledge as to the baseline outcomes in this population, independent of ROP.

Methods: Forty children from a population of infants screened for ROP (26 diagnosed; 7 treated) at Oregon Health & Science University (born less than gestational age (GA) of 31 weeks or with a birthweight (BW) less than 1500 grams) were recruited for neurodevelopmental testing. The mean ± standard deviation (SD) BW was 1000.0 ± 355.7 grams and mean ± SD GA was 27.8 ± 2.3 weeks. Mean ± SD age was 6.0 years ± 1.1 years (range 4 – 7.6) at time of testing. The Wechsler Preschool and Primary Scale of Intelligence (WPPSI-IV) performance-based assessment was used to provide Scale IQ (FSIQ), Verbal Comprehension (VCI) and Visual-Spatial (VSI) composite scores. Global Executive Composite (GEC) scores were assessed by having parents complete either the Behavior Rating Inventory of Executive Function for preschool children <5 years (BRIEF-P) or the BRIEF-2 for children >5 years. The Vineland-3 Domain-Level Parent/Caregiver Form provided motor skills scores (MOT). Univariate and multivariate linear regression was used to investigate whether there were correlations between BW, GA, or BW and GA and FSIQ, VCI, VSI, GEC, and MOT. Interactions between BW and GA were accounted for.

Results: In this cohort, LBW was a significant predictor of FSIQ (R^2: 0.38), VCI (R^2: 0.24), VSI (R^2: 0.26) and MOT (R^2: 0.41). GA was a significant predictor of FSIQ (R^2: 0.17), VSI (R^2: 0.13), GEC (R^2: 0.15) and MOT (R^2: 0.31). Together, BW and GA (and their interaction) were significant predictors of VSI (R^2: 0.38).

Conclusions: BW and GA have significant correlations with neurodevelopmental outcomes. Studies that evaluate neurodevelopmental outcomes as a result of ROP treatment need to account for potential confounding by prematurity, and other comorbidities of premature birth.

ABSTRACT BODY:

Purpose: Primary open angle glaucoma (POAG) is a heterogeneous disease for which the underlying molecular mechanisms and their associated traits are not well defined. We applied a soft clustering method, Bayesian nonnegative matrix factorization (bNMF), to genome-wide association study (GWAS) data to identify novel sets of known POAG genetic loci that cluster with endophenotypes potentially significant to POAG. Such clusters propose different mechanistic pathways and traits that could be causal to POAG, which we further investigated for gene enrichment in ocular cell types and biological pathways.

Methods: bNMF clustering emulates physiological relevance as individual genes can belong to more than one pathway, and accounts for trait direction of effect on POAG risk in the prepared standardized association matrix. bNMF was performed using 133 independent POAG variants from the largest European and cross-ancestry genome-wide association study (GWAS) meta-analyses of POAG. Endophenotypes were selected based on known or putative pathogenic mechanisms of POAG, and available GWAS summary statistics. Genes were mapped to POAG loci via e/sQTL colocalization analysis, and tested for single cell expression enrichment in anterior segment (AS), optic nerve head and retina, and enrichment in biological processes.

Results: Of 100 POAG-related traits identified, 33 met the inclusion criteria. bNMF identified 4 clusters with 5 to 39 POAG variants each (converging to N=4, 83.8% of 1000 iterations). Each cluster was represented by unique trait and direction of effect combinations. The strongest effects on POAG risk resulted from decreased plateletcrit, diastolic blood pressure and urate serum levels (cluster 2), and increased intraocular pressure and decreased corneal hysteresis (cluster 3). Genes in POAG loci of each cluster showed significant enrichment (FDR<0.1) in specific cell types and pathways, e.g. pericyte (AS) and Müller glia (retina) (cluster 2), and ciliary and iris fibroblasts (AS) and retinal astrocytes (cluster 3).

Conclusions: Soft clustering identified several trait clusters and cell types associated with POAG risk, suggesting functionally distinct disease subtypes and offering a genetically-informed path towards personalized diagnosis and treatment.

TITLE: Safety and Effectiveness of MicroPulse Transscleral Laser Therapy in Non-Incisional Eyes with Ocular Hypertension and Primary Open Angle Glaucoma

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Murtaza, University of Toronto Temerty Faculty of Medicine, Toronto, Ontario, CANADA|Q. Kaba, Cardiff University School of Medicine, UNITED KINGDOM|S. Somani, E. Tam, D. Yuen, Department of Ophthalmology and Vision Sciences, University of Toronto, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure: Fahmeeda Murtaza: Commercial Relationship: Code N (No Commercial Relationship) | Qayim Kaba: Commercial Relationship: Code N (No Commercial Relationship) | Sohel Somani: Commercial Relationship: Code N (No Commercial Relationship) | Eric S. Tam: Commercial Relationship: Code N (No Commercial Relationship) | Darana Yuen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is limited evidence on the use of MicroPulse transscleral laser therapy (TLT) in non-incisional eyes. This study evaluates and compares the safety and effectiveness of MicroPulse TLT in non-incisional eyes with ocular hypertension (OHT), early and moderate primary open angle glaucoma (POAG).

Methods: All consecutive eyes with OHT, early and moderate POAG that underwent MicroPulse TLT from May 2016 to March 2018 at a single outpatient clinic in Ontario, Canada were included. The Canadian Ophthalmological Society guidelines were used for staging glaucoma. Eyes were excluded if an incisional glaucoma procedure was performed prior to MicroPulse TLT. Laser settings were maintained at 80 seconds per hemisphere, 160 seconds per eye with a duty cycle of 31.3% and power range of 900-2800 mW. The primary outcomes included mean IOP reduction ≥20% from baseline, adverse events, and change in logMAR best corrected visual acuity (BCVA) from baseline. Secondary outcomes included change in topical medications from baseline, number of retreatments, and escalation to incisional glaucoma procedures during follow-up.

Results: A total of 150 eyes from 96 patients were included: 35 had OHT, 68 had early POAG, and 47 had moderate POAG. All cohorts experienced a significant mean IOP reduction at 1, 3, 6 and 12-month follow-ups ($p<0.05$). By 12-months, 71.4% of eyes with OHT, 69.7% with early POAG, and 48.3% with moderate POAG achieved an IOP reduction ≥20% from baseline. There were no cases of persistent inflammation, persistent hypotony, phthisis bulbi or sympathetic ophthalmia. At 12-months, the mean BCVA in the total cohort was unchanged from baseline (mean difference [MD]=0.01 ± 0.01, p=0.51). At 12-months, the mean number of topical glaucoma medications in the total cohort was unchanged from baseline (MD=0.30 ± 0.01, p=0.09). Sixteen eyes (10.7%) required retreatment within 4.5 ± 4.3 months of the initial laser treatment. Retreatment provided an additional 1.0 ± 7.0 mmHg of IOP reduction (p=0.155). By final follow-up, 4 eyes (2.7%) required escalation to incisional procedures.

Conclusions: MicroPulse TLT is a safe and effective adjunctive IOP-lowering treatment in non-incisional eyes with OHT, early and moderate POAG. Our results suggest that MicroPulse TLT may be used earlier in the treatment paradigm.

TITLE: Risk factors and Contact Lens Modality in Patients with Acanthamoeba Keratitis

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.C. Scanzera, H.H. Yoon, E. Shorter, E. Tu, Ophthalmology and Visual Sciences, Illinois Eye and Ear Infirmary, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Angelica Scanzera: Commercial Relationship: Code N (No Commercial Relationship) | Hannah Yoon: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Shorter: Commercial Relationship(s);Code F (Financial Support):Johnson & Johnson, BostonSight, Contamac, Art Optical, SynergEyes | Elmer Tu: Commercial Relationship(s);Code F (Financial Support):Dompe, Eversight, Oyster Point Pharma, GSK, Daiichi Sankyo

ABSTRACT BODY:

Purpose: Acanthamoeba keratitis (AK) is a rare but potentially visually devastating ocular infection. Diagnosis can be challenging, often resulting in misdiagnosis with delayed treatment. Individuals with history of contact lens use and improper lens handling including exposure to water or corneal trauma are at higher risk of infection.
The purpose of this study was to describe patient demographics, time from symptom onset to diagnosis, time from presentation to clinic to diagnosis and risk factors in patients diagnosed with AK at a tertiary care center.

Methods: Medical records of all patients evaluated at the Illinois Eye and Ear Infirmary (IEEI) between 2015 and 2020 with a diagnosis of AK were reviewed. Patients with a new diagnosis of AK during the study period were included. This study was approved by the University of Illinois at Chicago Institutional Review Board.

Results: There were 58 patients identified with AK including 5 patients (8.6%) with bilateral disease. Mean age was 38.7 years (range 12 to 80) with 55.2% females. The majority (94.8%) were contact lens wearers using soft lenses (65.5%) followed by corneal gas permeable (21.8%), hybrid (5.5%), and scleral lenses (1.8%). There was documented exposure to water including rinsing lenses in water, swimming in pools, lakes, hot tub use and showering in almost half of the patients (48.3%). Overnight lens use was documented in 29.3% including three orthokeratology lens users. Mean time from symptom onset was 44 days ± 51, and mean time from presentation at IEEI to diagnosis was 3 days ± 8. Confocal microscopy was performed on 48 patients and cysts consistent with acanthamoeba were present in 41 of those patients (93.2%) while cultures were positive in only 17 of 38 patients (44.7%).

Conclusions: In this case series, 35.5% of contact lens related AK cases were in rigid and hybrid lens users. Previous epidemiologic studies found that 85-88% of contact lens related AK infections are in soft lens users, and among U.S. contact lens prescribers, soft lenses consist of 95% of lens fits. This data suggests that the risk of AK in rigid and hybrid lens users may be increasing. A future well-designed case-control study may assist in evaluating the relationship between AK and different lens modalities.

ABSTRACT BODY:

Purpose: Sickle cell disease encompasses a spectrum of inherited hemoglobinopathies that have various ophthalmic manifestations, including SCR. WF SS-OCTA is a valuable tool to assess the extra-macular region compared to traditional OCTA. Herein, we aim to study the utility of WF SS-OCTA in SCR.

Methods: We conducted a single-institution observational study using WF SS-OCTA to obtain 3x3mm, 6x6mm, and 12x12mm scans centered on the fovea. The ARI Network (Zeiss Portal) was used to quantify vascular metrics such as vessel density (VD), vessel skeletonized density (VSD) in superficial (SCP), deep capillary plexus (DCP) and whole retina; and foveal avascular zone (FAZ) area, circularity and perimeter. Mixed-effects multiple regression models adjusting for age were used for statistical analysis.

Results: The median age was 59 (46-63.3) years. We analyzed 38 control eyes of 20 patients and 20 eyes of 11 patients with SCR: proliferative SCR (PSCR, n=5), non-proliferative SCR (NPSCR, n=9), and no SCR (NSCR, n=6). On 3x3mm scans, the PSCR group had decreased FAZ circularity vs the control (β=-0.15), NSCR (β=-0.15), and NPSCR (β=-0.11) groups ($p<0.05$). Importantly, the NSCR group had greater FAZ area vs controls (β=0.27, $p=0.04$). On 6x6mm scans, there was reduced SCP VD (NSCR β=-0.05; NPSCR β=-0.05, PSCR β=-0.04, all $p<0.05$) and VSD (NSCR β=-2.67; NPSCR β=-2.53, PSCR β=-2.41, all $p<0.05$) and whole retina VD (NSCR β=-0.04; NPSCR β=-0.04, PSCR β=-0.03, all $p<0.05$) and VSD (NSCR β=-2.09; NPSCR β=-2.18, PSCR β=-1.96, all $p<0.05$) for all groups compared to controls. NPSCR eyes also demonstrated reduced DCP VSD (β=-3.66) and VD (β=-0.07) vs controls ($p<0.05$). There was increased FAZ perimeter for NPSCR (β=1.64) and PSCR (β=1.06) vs controls ($p<0.05$). FAZ area was also increased for NSCR (β=0.28), NPSCR (β=0.36) vs controls, and NPSCR (β=0.17) vs the PSCR group (all $p<0.05$). On 12x12 scans, there was increased FAZ area for the NSCR group (β=0.31, $p=0.02$) vs controls.

Conclusions: Our results show that in patients with no evidence of SCR, there is an increased FAZ area vs control, suggesting a subclinical disease featuring early retinal capillary dropout. This study demonstrates reduction in VD/VSD and hence the potential benefits of utilizing WF SS-OCTA in SCR. In future, we aim to investigate changes in the periphery and its clinical significance using this imaging technology.

ABSTRACT BODY:

Purpose: The effect of immunosuppression on the survival of human embryonic stem cell (hESC) derived retina organoids (ROs) produced by a scalable cGMP compatible process was studied after transplantation to the subretinal space of Rho S334ter-3 retinal degeneration (RD) rats, and in vitro.

Methods: A Working Cell Bank (WCB) of CSC-14 hESCs (NIH 0284) was established using a scalable cGMP compatible process. RO sheets differentiated from hESCs were transplanted to 3 groups of rats: 1. Immunodeficient (nude) RD rats; 2. Immunocompetent RD rats; 3. Immunocompetent RD rats with immunosuppression. The survival of the transplants was monitored by Optical Coherence Tomography (OCT). Immunosuppressants (Tacrolimus [TAC] pellet implant and oral mycophenolate mofetil [MMF]) were applied to the rats in group 3. TAC levels in blood were determined by LC-MS and MMF/cytokine levels were monitored by Elisa. Cytostatic effects on target lymphocyte populations were evaluated by flow cytometry. Sections through transplants were stained with hematoxylin & eosin (H&E) and immunohistochemistry (IHC) with different markers. The effect of TAC and MPA on RO was tested by fluorescence lifetime imaging (FLIM) after exposure for 1 and 4 weeks. Visual function was tested by optokinetic testing (OKT).

Results: A WCB of hESCs was established from the MCB. In vitro immunogenicity tests showed that ROs are not likely to induce an immune response. IHC of ROs shows early lamination and development of retinal cell progenitors. No significant difference was found between ROs exposed to immunosuppressants and controls. The transplants developed different retinal cells including photoreceptors; integrated with the host retina; and survived for more than 6 months in immunocompromised rats. CD8 T-cells obliterated donor cells in immune competent rats without immunosuppression after 2 months post-surgery. Therapeutic levels of immunosuppressant remained in the blood and helped transplants survive in the host for 6 months. OKT showed improvement of visual function in transplanted rats compared to non-surgery controls.

Conclusions:

Retina organoids matured, developed photoreceptors, and improved visual acuity after transplantation. Suppression of host CD8 T-cells may be necessary for transplant long term survival. Activity of microglia and macrophages alone may not be detrimental to transplant survival.

SUBMITTER (NAME ONLY): Krishna Shanmugam

TITLE: Investigating the The Role of Neoplastic Disorders in the Development of Open-Angle Glaucoma: A Big Data Approach

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.P. Shanmugam, A. Tadjali, Texas A&M University Health Sciences Center, Bryan, Texas, UNITED STATES|C. Murugesan, M. Raju, University of Missouri, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Krishna Shanmugam: Commercial Relationship: Code N (No Commercial Relationship) | Armand Tadjali: Commercial Relationship: Code N (No Commercial Relationship) | Charunetha Murugesan: Commercial Relationship: Code N (No Commercial Relationship) | Murugesan Raju: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Open-angle glaucomas are challenging and usually silent disease processes that often present with advanced optic nerve damage and visual field defects. In the current study, we present a novel population-based data mining analysis to gain a deeper
understanding of glaucoma risk factors through innovations in big data science. This study aims to more clearly define whether there is a correlation between neoplastic conditions and other assorted demographic variables on the development of open-angle glaucoma.

Methods: Using deidentified electronic health records (EHR) from the vast i2b2 database from the University of Missouri, ICD (International Classification of Disease) codes based on inclusion and exclusion criteria of the specific study cohorts were examined. Cumulatively, 14,212 patient records were analyzed. We applied a Pearson correlation analysis and stepwise regression analysis to find a possible association between glaucoma and selected study variables.

Results: This study specifically found that neoplasms of skeletal and connective tissue have an increased association ($p<0.05$) with open-angle glaucomas as compared to any other neoplastic processes. No other oncologic conditions appeared to show a similar association. Similarly, in our cohort, there is an association ($p<0.01$) between glaucoma and lifelong non-smoking status and patients with any previous history of smoking. This is particularly interesting, as patients who were current smokers were not associated with an increased glaucoma risk. Lastly, this study found that African American individuals have an incredibly statistically significant ($p<0.01$) risk of glaucoma development versus other study populations.

Conclusions: In our analysis of a large subset of patients in a vast database, glaucoma was associated with neoplasms of the connective tissue and bone more than any other neoplastic process. A possible explanation for this could be the fact that there is a common ectodermal embryology between these structures. Furthermore, African Americans and nonsmokers/former smokers have been associated with an increased risk for glaucoma, when compared with current smokers, and these facts should be examined in larger scale studies. Without a doubt, this study demonstrates the vast potential of applying data mining methods for risk assessments using large-scaled EHR data.

TITLE: The Effect of Teprotumumab on Ocular Surface Symptoms in Thyroid Eye Disease

SESSION TITLE: Thyroid eye disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Cale, E. Osias, P. Singh, D. Rootman, Orbital and Ophthalmic Plastic Surgery, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Mario Cale: Commercial Relationship: Code N (No Commercial Relationship) | Ethan Osias: Commercial Relationship: Code N (No Commercial Relationship) | Pallavi Singh: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Rootman: Commercial Relationship(s);Code C (Consultant/Contractor):Horizon Pharmaceuticals

ABSTRACT BODY:

Purpose: Dry eye syndrome occurs in up to 85% of patients with thyroid eye disease (TED), and it is unclear how teprotumumab affects this symptomatology. We tested the hypothesis that treatment with teprotumumab would significantly reduce both subjective and objective ocular surface disease symptoms in TED patients.

Methods:

This was a retrospective cohort study of adult patients with thyroid eye disease treated at the University of California, Los Angeles since 2014. We assessed the effect of teprotumumab therapy on subjective ocular surface symptoms as measured by the Ocular Surface Disease Index (OSDI), a previously validated questionnaire for dry eye syndrome. The degree of change from baseline OSDI score was compared between patients that received teprotumab and baseline score-matched control patients that never received it. Change in objective dry eye manifestations like punctate epithelial erosions and superior limbic keratopathy were also studied. Statistical analysis was performed using an independent two-tailed t test with an alpha level of 0.05.

Results: We identified 18 patients (14 females, 4 males) treated with teprotumumab with a mean age of 53.5 (SD=14.9), and 18 controls (15 females, 3 males) with a mean age of 49.8 (SD=13.3). The average time from baseline OSDI to the next patient visit was 5.3 months (SD=3.0). Patients treated with teprotumumab experienced a statistically significant decrease of 15.4 (SEM=3.6) in their OSDI score compared to the controls (p=0.002). The change in severity of punctate epithelial erosions or superior limbic keratoconjunctivitis did not differ between groups.

Conclusions: Teprotumumab was effective in significantly mitigating clinical ocular surface symptoms, although the effect on objective physical exam findings was negligible. Given the complexity of dry eye syndrome and the importance of the subjective experience of disease, our findings illustrate a possible benefit of this therapy.

TITLE: Quadrifocal diffractive lens design for presbyopia correction

SESSION TITLE: Crystalline lens and IOLs

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G. Yoon, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|S. Bang, Biomedical Engineering, University of Rochester, Rochester, New York, UNITED STATES|J. Lyu, Institute of Optics, University of Rochester, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Jiakai Lyu: Commercial Relationship: Code N (No Commercial Relationship) | Seungpil Bang: Commercial Relationship: Code N (No Commercial Relationship) | Geunyoung Yoon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although bifocal and trifocal diffractive intraocular lenses are effective in correcting presbyopia, the fact that retinal image quality is significantly degraded between the designed foci remains a limitation. One potential solution can be to generate more foci, resulting in improved through-focus image quality. The goal of this study is to evaluate a new method to design a quadrifocal diffractive presbyopia-correcting ophthalmic lens.

Methods: To design a quadrifocal lens with focal points at 0, 1, 2 and 3 diopters (D), two bifocal diffractive lenses, one for 0 and 2D and the other for 1 and 3D, are radially cut into rings based on a threshold value in wavefront phase (one below and one above). The rings are combined to be a quadrifocal lens. To validate the performance of the quadrifocal lens, an optical bench testing system equipped with a spatial light modulator generating the diffractive design was constructed. The quadrifocal lens was compared against a typical trifocal diffractive design (foci at 0, 1.5 and 3D) for a 4mm pupil with 579nm monochromatic light. An image quality metric, area under modulation transfer function (areaMTF) calculated from the collected images of a letter E chart through the lens designs, was used to quantify retinal image quality at various object distances ranging from 0 to 3D.

Results: Both simulation and bench testing showed that the quadrifocal lens created peak image quality at the designed foci. The quadrifocal design provided significantly better image quality at 1 and 2D than the trifocal design at the cost of slight image quality degradation at 0 and 3D. As expected, image quality at 1.5D was significantly better with the trifocal lens. Both diffractive designs showed similar overall through-focus image quality represented by the sum of the areaMTF values between 0 and 3D. Additional simulation demonstrated that by controlling the relative phase and ring width between the two bifocal designs, the relative image quality at the four foci could be manipulated as needed.

Conclusions: A newly designed quadrifocal diffractive lens for presbyopia correction was proposed. The results demonstrated that generating more than 3 foci was feasible, without sacrificing overall through-focus image quality.

ABSTRACT BODY:

Purpose: Diagnosing cataract usually requires in-person evaluation by an ophthalmologist. However, many individuals undergo color fundus photography (CFP) outside ophthalmology clinics, which represents an opportunity towards more accessible diagnosis by developing automated cataract detection methods. Therefore, the purpose of this study was to develop an explainable deep learning network that can detect cataract from color fundus photographs (CFPs) obtained from the Age-Related Eye Diseases Study 2 (AREDS2).

Methods: A dataset of 17, 514 CFPs was obtained from 2,573 AREDS2 participants. The dataset comprised 8,681 CFPs from eyes with cataract and 8,833 CFPs from eyes without cataract. The ground truth labels were transferred from slit lamp exams of nuclear cataracts conducted by ophthalmologists and from reading center gradings of the anterior segment photos (red reflex photos) for evaluating cortical and posterior subcapsular cataracts. The dataset was divided into training, validation, and testing datasets (70%, 20%, and 10% participants, respectively). A deep learning network was developed using separable convolutions and residual connections. The network performance was compared to that of three ophthalmologists. The network was visualized using Gradient Class Activation Maps (Grad-CAMs) where areas of high signal correspond to the CFP pixels that contributed most to the network decision.

Results: The network achieved performance scores (with 95% CI) of 0.6683 (0.6531, 0.6838), 0.6691 (0.6536, 0.685), 0.6686 (0.6533, 0.6842), 0.6686 (0.6533, 0.6842) compared to that of the combined ophthalmologists of 0.6025 (0.5100, 0.7000), 0.6119 (0.5085, 0.7123), 0.5988 (0.5074, 0.6895), and 0.5988 (0.5074, 0.6895) for accuracy, precision, recall, and AUC, respectively. Qualitative analysis of the Grad-CAMs, of correctly graded CFPs, showed that areas of high signal in CFPs without cataract and areas of low signal in CFPs with cataract corresponded to retinal blood vessels, as shown in Fig. 1.

Conclusions: The proposed network outperformed three ophthalmologists in the detection of cataract from CFP, which may increase the accessibility of cataract diagnosis. The detections were generally explainable where the retinal blood vessels seemed to be an important diagnostic feature.

TITLE: The Sensitivity and Specificity of FLIO (Fluorescence Lifetime Imaging Ophthalmoscopy) when Imaging Patients with MacTel

SESSION TITLE: Macular Diseases excluding AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Sauer, A. Vitale, P.S. Bernstein, University of Utah Health John A Moran Eye Center, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Lydia Sauer: Commercial Relationship(s);Code C (Consultant/Contractor):Tesseract | Alexandra Vitale: Commercial Relationship(s);Code C (Consultant/Contractor):Tesseract | Paul Bernstein: Commercial Relationship(s);Code C (Consultant/Contractor):Tesseract;Code S (non-remunerative):Heidelberg Engineering

ABSTRACT BODY:

Purpose: Macular telangiectasia type 2 (MacTel) is a retinal disease that leads to central visual distortions such as metamorphopsia and central scotomas in affected individuals. The clinical diagnosis of MacTel can be challenging, and the use of multimodal imaging approaches improves diagnostic potential. Fluorescence lifetime imaging ophthalmoscopy (FLIO) has proven to be a useful tool in diagnosing this condition. The aim of this study is to investigate all suspected MacTel patients that received FLIO imaging in order to determine sensitivity and specificity of FLIO in our clinical practice.

Methods: From March 2018 until January 2022, 161 patients were referred for FLIO imaging at the Moran Eye Center to be evaluated for MacTel. A prototype Heidelberg Engineering FLIO was used to obtain autofluorescence lifetimes in short (SSC, 498-560 nm) and long (LSC, 560-720 nm) spectral channels. All patients received a comprehensive ophthalmologic exam and most patients received standard clinical imaging including optical coherence tomography (OCT).

Results: 119 patients had characteristic patterns of MacTel on FLIO imaging and the diagnosis of MacTel was clinically confirmed. Images of 5 patients were inconclusive on FLIO imaging, due to severe cataracts (3 cases) or poor image quality (2 cases). All of these 124 patients were clinically diagnosed with MacTel. The remaining 37 patients did not show characteristic signs of MacTel in FLIO imaging. None of these patients were diagnosed with MacTel, and further testing revealed the presence of other retinal diseases, such as cone dystrophy, tamoxifen retinopathy, hydroxychloroquine toxicity, or age-related macular degeneration.

Conclusions: The ability of FLIO to detect disease related changes in patients with MacTel has proven to be diagnostically advantageous in clinical practice. In our cohort of 161 patients evaluated for MacTel, FLIO has a high sensitivity (96%) and specificity (100%) when determining if a patient has MacTel or not.

TITLE: TNF-α stimulation enhances the neuroprotective effects of gingival MSCs derived exosomes in retinal ischemia-reperfusion injury via the MEG3/miR-21a-5p axis

SESSION TITLE: Neuroprotection, blood flow and ischemia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Yu, Y. Zhuo, Sun Yat-Sen University Zhongshan Ophthalmic Center, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Ziyu Yu: Commercial Relationship: Code N (No Commercial Relationship) | Yehong Zhuo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We examined TNF-α-stimulated gingival MSC (GMSC)-exosomes for their neuroprotective and anti-inflammatory effects in retinal IRI. We further aim to explore the crucial factors and pathways involved in protective mechanisms of GMSC-derived exosomes.

Methods: In this study, exosomes from the CM of GMSCs were isolated by ultracentrifugation. Exosomes from conditioned culture medium (CM) of MSCs stimulated by TNF-α were injected to cell and the vitreous of mouse model. The effects of TNF-α-stimulated gingival MSC (GMSC)-exosomes (TG-exos), in modulating inflammatory microglia and alleviating apoptosis was detected by PCR, western blot analysis, immunofluorescence staining assay.

Results: The results showed that intraocular injection of TG-exos into mice with IRI notably reduced inflammation and cell loss than that with G-exos (GMSC-exosomes). Similar results were observed in vitro. Additionally, with the microRNA (miR) arrays, it was found that miR-21-5p acted as a crucial factor in TG-exos for neuroprotection and anti-inflammation. Following target prediction and dual luciferase assay suggested that miR-21-5p played a role by combining with programmed cell death 4 (PDCD4), which was regulated by the long non-coding RNA (lncRNA) maternally expressed gene 3 (MEG3) as a competing endogenous RNA (ceRNA).

Conclusions: This study demonstrates a new therapeutic pathway for neuroprotection against IRI by delivering miR-21-5p-enriched exosomes through MEG3/miR-21- 5p/PDCD4 axis and paves the way for the establishment of a cell-free therapeuticapproach for glaucoma.

TITLE: Signal Quality and Repeatability of Two Corneal Electrodes Used with a Handheld Electroretinogram System

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Patangay, J.R. Hetling, Bioengineering, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|J.R. Hetling, Ophthalmology and Visual Science, University of Illinois at Chicago College of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Shresta Patangay: Commercial Relationship(s);Code E (Employment):Retmap, Inc. | John Hetling: Commercial Relationship(s);Code S (non-remunerative):Retmap Inc;Code P (Patent):RetMap, Inc. US 10,952,630 B2;Code I (Personal Financial Interest):Retmap Inc

ABSTRACT BODY:

Purpose: This study evaluated the performance of two corneal electroretinogram (ERG) sensors when used with a hand-held ERG system. Conductive thread-type sensors (DTL Plus, Diagnosys LLC) and prototype disposable contact lens sensors (RM Electrode, provided by RetMap Inc.) were used. The hypotheses were that the RM sensor, which makes electrical contact with the cornea only, would provide signals of higher signal to noise ratio (SNR) and improved repeatability (responses within a test, and across repeated tests) when compared to the DTL sensor, which makes electrical contact with the cornea and other nearby tissues.

Methods: Three normally-sighted subjects (six eyes) participated. Following administration of a corneal numbing agent the DTL was installed in one eye and the RM in the other eye (randomly assigned). Using the handheld RETeval system (LKC Technologies) the “ISCEV 6 Step Dark First Td” protocol (no pupil dilation) was followed, with 10 min dark- and light-adaptation periods. After the protocol was complete the sensors were removed, new sensors of the opposite type were installed in each eye, and the protocol was repeated. The entire procedure was carried out on two consecutive days. Repeatability was quantified as the root mean squared error (RMSE) over a 150 ms post-stimulus interval. RMSE was calculated between responses to repeated stimuli within a test, and between averaged waveforms obtained in tests performed on consecutive days.

Results: For the 3.0 dark-adapted stimulus (85 Troland seconds), RMSE values for repeated tests were lower in 67% of eyes with the RM sensor, with an average reduction of 40% compared to values obtained with DTL sensors. RMSE values for repeated stimuli within a test were lower in 100% of eyes with the RM sensor, with an average reduction of 59% compared to values obtained with DTL sensors. SNR values for individual responses in eyes with the RM sensor were increased by 128% (4.28 dB), on average, compared to values obtained with DTL sensors.

Conclusions: A disposable sensor designed to improve the consistency and location of corneal contact (RM) can improve repeatability of responses compared to thread-type ERG sensors. Improved repeatability has the potential to shorten ERG test times and narrow reference ranges used for diagnosis and monitoring.

TITLE: Evaluating the outcomes of dried vs cryopreserved amniotic membrane grafting in the treatment of corneal epithelial defects

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Tian, C. Wisely, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: James Tian: Commercial Relationship: Code N (No Commercial Relationship) | Clayton Wisely: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Amniotic membrane grafts (AMGs) have been used to provide nutritious and anti-inflammatory scaffolding to the cornea surface to promote epithelial wound healing. While initial AMGs were first prepared with cryotherapy, there are logistical advantages of using dried AMGs that can be stored at room temperature. However, there is insufficient clinical data on the outcomes of amniotic membrane grafting between dried vs cryopreserved AMGs for specific indications. Thus, we aim to compare the resolution rate of corneal epithelial defects when treated with a dried vs cryopreserved AMGs.

Methods: A search for CPT codes for AMG placement was performed in our institution's electronic health record, and the corresponding charts were reviewed to isolate patients who received an AMG for a corneal epithelial defect. The type of (dried vs cryopreserved) AMG, presenting best-corrected visual acuity (BCVA), indications for AMG, and anterior segment exam data were collected. Patients were separated into a "fully healed", "partially healed", or "no improvement" based on clinical documentation. Statistics were computed with Chi-square and Student's t-test.

Results: A total of 43 charts were reviewed of patients who underwent AMG placement for corneal epithelial defects. 32 patients underwent dried AMG placement, 11 underwent cryopreserved AMG placement. The indications ranged from persistent epithelial defects after corneal transplantation or superficial keratectomy to herpetic neurotrophic keratitis or ocular cicatricial pemphigoid. The mean age of the dried AMG group was 68 and the mean age of the cryopreserved group was 64. The mean presenting BCVA was higher in the dried AMG group (20/160-20/200) than in the cryopreserved AMG group (20/400-20/600). The rate of full or partial epithelial healing was 94% (30/32) for the dried AMG group and 91% (10/11) for the cryopreserved AMG group (p=0.75).

Conclusions: The logistically simpler dried AMG and the cryopreserved AMG showed similar outcomes when used to treat corneal epithelial defects.

ABSTRACT BODY:

Purpose: The transition from normality to early drusen (≥ 20 small hard drusen or drusen ≥ 63 µm in diameter) has received little attention. As hypothesized by some researchers, small hard drusen precede the development of large drusen. Consequently, they should share similar genetic and environmental associations. The purpose was to research, by examining lesion-by-lesion, the genetic and environmental factors associated with the 20-year incidence of early drusen and whether small hard drusen are associated with large drusen.

Methods: A single-center, 20-year follow-up cohort study comprising 138 twins at the Department of Ophthalmology, Rigshospitalet. Examinations included biometry, fundus optical coherence tomography, and fundus photography. Each macula was classified, at baseline and follow-up, as having 1) < 20 small hard drusen, 2) ≥ 20 small hard drusen, 3) drusen ≥ 63 µm, and 4) ≥ 20 small hard drusen combined with drusen ≥ 63 µm.

Results: The median age was 59 (range 41 - 66) years. Of 25 (18.1%) incident cases, 7 had developed ≥ 20 small hard drusen, 18 had developed drusen ≥ 63 µm, whereas none had developed the combination of the two traits. Smoking was associated with incident ≥ 20 small hard drusen ($p = 0.04$) and with incident drusen ≥ 63 µm ($p = 0.003$). At baseline, having≥ 20 small hard drusen was associated with incident drusen ≥ 63 µm at follow-up ($p = 0.02$). Development of drusen ≥ 63 µm was attributable to 49% genetic effects and 51% environmental effects.

Conclusions: Incident cases with ≥ 20 small hard drusen or drusen ≥ 63 µm were strongly associated with smoking and genetic predisposition. Having ≥ 20 small hard drusen at baseline was associated with having developed incident drusen ≥ 63 µm after 20 years.

ABSTRACT BODY:

Purpose: Congenital stationary night blindness 1 (CSNB1) is caused by a mutation in the NYX gene, which encodes for nyctalopin, a protein located on the dendrites of bipolar cells that is critical in phototransduction. This mutation results in severe dysfunction within the ON visual pathway while the integrity of the OFF pathway remains relatively intact. While the cause and effect of this mutation are known, how the dysfunction is represented at the level of the retinal ganglion cell (RGC) population remains unclear.

Methods: We crossed nob knockout mice with Thy1-GCaMP6f mice, which label a subset of RGCs with the calcium indicator GCaMP6f. Using two-photon microscopy, we recorded calcium responses of wild-type Thy1-GCaMP6f and Nob/Thy1-GCaMP6f RGCs while presenting the retina with a variety of visual stimuli. These responses were processed and analyzed using MATLAB.

Results: Of the cells labeled by GCaMP6f, there are approximately half as many light-responsive RGCs in the nob retina compared to the wild-type. In the wild-type RGC population, there is a mix of ON, OFF, and ON-OFF cells, while the nob population is composed almost entirely of OFF cells. Unlike in the wild-type retina, when ON responses are present in nob RGCs, they are significantly delayed. The receptive fields of the nob RGCs are slightly smaller on average than wild-type RGCs. There appears to be a greater degree of direction selectivity in the nob RGC population than the wild-type population. Finally, there is a significant number of non-light evoked responses present in the nob population that is not seen in the wild-type.

Conclusions: There are significant functional differences between the nob and wild-type RGC populations in terms of polarity, receptive field, direction selectivity, and responsiveness to light stimuli.

ABSTRACT BODY:

Purpose: Dry Eye Disease (DED) is a common condition whose pathophysiology and treatment are still actively being researched. Absence of a universally accepted animal model for DED research poses a barrier to further development of our understanding. All animal models have limitations in how they translate to the human condition in both disease physiology and assessment. Here we show the ability of an advanced keratography unit (AKU) already used in clinical practice to effectively measure DED status in rabbits.

Methods: Numerous measures of DED using an advanced keratography unit (AKU) were made before and after DED was induced in 15 New Zealand White (NZW) and 4 Dutch Belted (DB) rabbits with concanavalin A. Standard DED measures included first and average non-invasive keratographic break-up time (NIKBUT), tear meniscus height (TMH), meibomography, and Tearfilm dynamic (TFD). Other measures included palpebral fissure height (PFH), temporal angle size (TAS), and corneal irregularity (CI). A normative dataset for parameters in each species was created.

Results: First and average NIKBUT, PFH, and TAS (9.14±5.48, 17.14±2.94, 10.7±1.0, 122 ± 10 respectively) significantly decreased following DED induction (4.54±2.63, 12.93±3.33, 7.1±3.0, 81±32 respectively; all $p<0.001$). TMH (0.21±0.03) and CI (0.021± 0.008) both increased (0.27±0.09, 0.040±0.017 respectively; both $p<0.003$) after DED induction. The data were similar if looking at DB and NZW groups separately. Meibomography and TFD were not useful discriminating DED.

Conclusions: We present normative data values for a panel of DED and other metrics collected with an AKU. Statistically significant changes in the expected direction were observed for NIKBUT, PFH, TAS and CI following induction of DED. The significant change in TMH was in the wrong direction suggesting other compensatory responses are occurring. The results indicate this AKU (Oculus Keratograph 5M) can measure DED status in this rabbit model. AKU technology has potential to improve diagnostic capability in DED research using rabbit models. This non-invasive, objective quantification of DED can improve translational research allowing for improved fidelity between methods of DED assessment in rabbit and human DED. Such benefits may be especially useful in studies new pharmacologic treatments for DED.

ABSTRACT BODY:

Purpose: To determine the efficacy of radial full-thickness fixation sutures in DSEK among patients considered at high risk for graft dislocation.

Methods: A retrospective chart review was performed to identify patients who underwent DSEK at Mayo Clinic between January 2015 and January 2021. Cases at high risk of graft dislocation were defined as eyes that had prior trabeculectomy, glaucoma drainage devices, absence of lens capsule, vitrectomy, or penetrating keratoplasty. The primary outcome was graft dislocation rate (defined as the need for rebubble) among eyes that had graft fixation with four radial full-thickness 11-0 nylon sutures versus no fixation sutures.

Results: Three hundred fifty-seven DSEK surgeries occurring among 323 eyes of 242 patients were reviewed, and 181 were considered high risk. Of the high risk cases, 66 had graft suture fixation and 115 were unsutured. Baseline demographics and ocular comorbidities were comparable. Sutured DSEKs had a graft dislocation rate of 5% (n=3), versus 14% (n=16) of unsutured grafts ($p<0.05$). In the sutured group, one case of dislocation also had primary graft failure which may have contributed to failure to attach.

Conclusions: DSEK is a useful graft procedure for patients with corneal endothelial failure and complicated anatomy. We showed that intraoperative suture fixation of the graft reduces graft dislocation rates in these high-risk eyes.

ABSTRACT BODY:

Purpose: Perform composite parameter sensitivity analysis, elucidate relative contribution of two parallel drug penetration pathways into eye from topically applied drops, towards establishing an oBCS and refining its framework.

Methods: Experimentally determined intrinsic solubility values of drug substances found in commercially available eye drops were compiled. A subset of forty drugs with available in vitro corneal (Cr) and conjunctival (Cj) tissue permeability (Papp) data, expressed as CrPapp/CjPapp, were used to plot sensitivity surfaces as a function of total topical ophthalmic dose (Do). Extent of aqueous humor (AqH), iris-ciliary body (ICB) and systemic exposure was calculated 0-20 minutes (e.g. $AUC_{0\text{-}20min}$) using OCAT™ simulated topical ophthalmic dosing as a function of corneal vs. conjunctival penetration access, and nasolacrimal drainage. Do and CrPapp/CjPapp parameter sensitivity analysis (PSA) were performed on 40 drugs to assess influence of corneal/conjunctival permeability, dose/solubility ratios on extent of absorption into eye vs. systemic.

Results: Contribution of the corneal route of absorption was dominant at nearly 90% fraction of dose reaching AqH for all compounds, while relatively low corneal permeability ones displayed up to 90% dependence of their ICB exposure on conjunctival access. Similarly, Do displayed up to 40% dependence on ICB access via conjunctival absorption, however was insensitive towards AqH access via corneal route of penetration. Contribution of nasolacrimal drainage towards systemic exposure displayed up to 15% dependence specifically on compounds with corneal penetration route preference as a function of increasing Do, while the opposite was true for compounds with conjunctival penetration route preference.

Conclusions: A oBCS is proposed in FIGURE. Pragmatic limitations in ocular bioanalysis result in challenges for bioequivalence establishment between different topical ophthalmic formulations of the same drug substance. There is potential value for computational model integrated biopharmaceutics in formulation design, optimization, and performance prediction.

ABSTRACT BODY:

Purpose: To investigate agreement of glaucoma progression diagnosis between optic disc and macula by regression analysis of retinal structures measured with spectral-domain optical coherence tomography (SD-OCT) in a prospective observational cohort study.

Methods: Primary open angle glaucoma patients with visual field defect above -18dB of mean deviation value were included in this prospective study. Exclusion criteria were eyes with ocular diseases including cataract, abnormality history of intraocular surgery except successful glaucoma surgery, and the onset of other ocular diseases during study period that may influence the SD-OCT measurement. The circum-papillary retinal nerve fiber layer (cpRNFL) thickness and macular ganglion cell complex (GCC) thickness were measured using SD-OCT (NIDEK RS-3000 Advance) during three years with arbitrary intervals less than six months. Linear regression analysis of cpRNFL thicknesses in temporal, superior, nasal and inferior quadrants and GCC thicknesses in superior macula and inferior macula were performed with build-in software of the SD-OCT. A statistically significant thinnings in any area were defined as glaucoma progression ($P < 0.05$).

Results: 48 eyes of 48 glaucoma patients were included. Age and mean deviation at baseline visit were 61 ± 8.7 (mean ± standard deviation) years old and -5.7 ± 4.8dB. cpRNFL thinning rates (thickness at baseline) in temporal, superior, nasal and inferior quadrants were -0.38 ± 1.21 μm/y (57.9 ± 17.5 μm) , –1.49 ± 2.07 μm/y (90.3 ± 21.2 μm), 0.0 ± 1.4 μm/y (74.3 ± 14.4 μm) and -0.21 ± 1.63 μm/y (.2 ± 27.8 μm), respectively. GCC thinning rates (thickness at baseline) in suprerior and inferior macula were -0.18 ± 0.84 μm/y (84.6 ± 11.8 μm) and -0.07 ± 0.83 μm/y (74.7 ± 15.5 μm). Twenty four and 17 eyes were diagnosed as glaucoma progression by by cpRNFL and GCC, respectively, those were overlapped in 11 eyes. Kappa value was 0.21.

Conclusions: Agreement of glaucoma progression diagnosis was fair between cpRNFL thinning and macular GCC thinning.

TITLE: Decreased cone density in circular retinal regions at the outer edge of full thickness macular hole edema in adaptive optics imaging

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. CHEN, Ophthalmology and vision sciences, University of Toronto, Toronto, Ontario, CANADA|L. CHEN, Kensington eye institute, University of Toronto, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure: LINA CHEN: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: To introduce a method for analyzing adaptive optics (AO) imaging data on the full thickness macular hole (FTMH) and compare the cone density at the corresponding retinal regions surrounding the outer edge of para-macular hole edema (OEME) between the eyes with the FTMH versus the contralateral non-pathological eye within individual patients.

Methods: Method: Twenty-two patients (n=22) between the ages 53 and 73 years were recruited at the Kensington Eye Institute, Toronto. Each patient had one eye diagnosed with FTMH and the contralateral eye with no pathology. The AO images from 44 eyes were captured using rxt1 AO retinal camera. Nine images of each retina was overlapped covering 8°X8° central retina. The raw fragments of 4°X4° images were aligned to create a montage with developer-provided software. ImageJ was used for creating a grid. On the FTMH montage, a circle outlining OEME, and two perpendicular lines from diagonal meridians by 45° crossing the center of the macular hole were drawn. On the montage of the contralateral eye, a circle delineating the foveal avascular zone (FAZ), two lines with the same features as those on FTMH montage crossing the center of FAZ were drawn. The grid was created by overlaying the two lines from each montage. The created grid was overlaid on each montage. And the region of interest (ROIs) were sampled and compared with the guidance of the grid.

Results: Results: Of raw images from 22 eyes with FTMH, montage creation failed in 15 eyes (15/22, 68%), which was remarkably higher than contralateral eyes (P=0.01). The shifted fragment images were found in 38.8 % of total images taken from the eyes with FTMH, which was significantly higher than contralateral eyes (7.7%) (P=0.001). The cone density in 4 quadrants by OEME was decreased significantly than the contralateral corresponding retina (p=0.0004). Furthermore, the negative correlation between cone density and spacing at same regions was found in FTMH. (r=0.553, CI 95% [-0.79,-0.16], P=0.009).

Conclusions: Conclusion: The method of grid overlaying on the montage image was applicable to analyzing the AO imaging acquired from eyes with FTMH. Utilizing the grid, we found the cone density in circular retinal regions at the outer edge of ME was significantly decreased in adaptive optics imaging, which indicated that disturbance of the cones may occur outside OEME.

ABSTRACT BODY:

Purpose: Asymmetry among the ETDRS quadrants on en-face OCTA metrics (superficial [SRL] and deep retinal layer [DRL] perfusion density [PD] and vessel density [VD]) allows for intra-eye comparisons and possibly mitigates inter-eye variabilities such as refractive error, age, axial length, and magnification. Herein, we assess the effect of the level of diabetic retinopathy (DR) on quadrant asymmetry (QA) with en-face OCTA

Methods: 90 eyes (60 patients) [27 non-diabetic (noDM); 12 diabetics without DR (noDR); 11 mild, 10 moderate (mod) and 7 severe (sev) non-proliferative DR (NPDR); and 23 proliferative DR (PDR)] underwent 3x3mm OCTA scans (signal >7, fovea-centered and auto-segmented for SRL/DRL). QA was defined as the max-min value among 4 ETDRS quadrants for a given eye in terms of OCTA metrics for the SRL and DRL and was compared to DR severity by linear regression including fixed effects for each individual eye

Results: Mean age was 55.5 years (range 24-88) with 60% male. QA for SRL VD was 1.87, 1.95, 1.69, 2.37, 2.38 and 3.13 for noDM, noDR, mild, mod, sev and PDR, respectively. QA for SRL PD was 0.028, 0.035, 0.028, 0.046, 0.045 and 0.061, for DRL VD was 2.17, 1.76, 1.78, 2.38, 2.90 and 3.25, and for DRL PD was 0.037, 0.036, 0.033, 0.056, 0.071 and 0.069 for noDM, noDR, mild, mod, sev and PDR, respectively. Linear regression demonstrated for every step increase in DR severity, there was a 0.34 increase in QA ($p<0.001$) for SRL VD, +0.008 SRL PD ($p<0.001$), +0.41 DRL VD ($p<0.001$), and +0.010 DRL PD ($p<0.001$). QA for both SRL VD and PD were significantly higher in eyes with sev or PDR when compared to noDM or noDR eyes (+0.23 and +0.004, $p<0.001$). QA for both DRL VD and PD were significantly higher in eyes with mild or mod when compared to noDM or noDR eyes (+0.15, $p=0.04$ and +0.003, $p=0.02$)

Conclusions: DR severity affects PD and VD more asymmetrically across the 4 ETDRS quadrants with a linear increase in QA for each worsening level of DR. Clinically significant increase in QA occurs when eyes are worse than mod NPDR in the SRL and > mild NPDR in the DRL. Individual intra-eye metrics such as QA can be utilized to quantify DR severity without concerns for inter-eye variabilities that could affect the reproducibility and reliability of OCTA quantification

TITLE: Are perioperative blood pressure & blood glucose risk factors for poor surgical outcomes after 27-gauge vitrectomy for diabetic tractional detachments?

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Ambati, X. Cai, R. Duong, Y. Shildkrot MD, University of Virginia School of Medicine, Charlottesville, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Naveen Ambati: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoyu Cai: Commercial Relationship: Code N (No Commercial Relationship) | Ryan Duong: Commercial Relationship: Code N (No Commercial Relationship) | Yevgeniy Shildkrot MD: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Extremes in perioperative blood pressure and blood glucose are known risk factors for adverse outcomes after general surgical interventions. In the field of ophthalmology, there is little literature studying these parameters as risk factors. We performed a retrospective case series analysis to determine whether blood pressure and blood glucose on the day of surgery are associated with adverse outcomes in the postoperative period after 27-gauge (27g) vitrectomy for diabetic tractional retinal detachments (DM-TRD).

Methods: Data including peri/intraoperative blood pressure, fasting blood glucose (FBS), and postoperative visual and anatomic outcomes of 110 eyes that underwent 27g vitrectomy for repair of DM-TRD from 2013-2020 were evaluated. Logistic regression was performed to determine risk factors.

Results: Average age of the patient population was 45.33±12.07 years. Intraoperative complications included two cases of choroidal detachments. Of the patients who followed up on postoperative month six, 91.3% had an attached retina. Re-detachment was seen in 10.9% of cases, most often by postoperative month one. Pre-operatively, 80.2% of patients were legally blind compared to 56.3% at postoperative month 6 ($p<.001$). Higher maximum intraoperative mean arterial pressure (MAP) was associated with legal blindness at postoperative month six ($p = 0.010$). Though borderline, higher perioperative MAP was associated with fewer Snellen lines of improvement by postoperative month six ($p = 0.040$). Perioperative and intraoperative blood pressures were not a risk factor for poor anatomic outcomes in the postoperative period. Further, perioperative FBS was not a risk factor for poor visual and anatomic outcomes in the postoperative period.

Conclusions: Increased maximum intraoperative MAP is associated with worse visual outcomes. Blood pressure on the day of surgery was not a risk factor for poor anatomic outcomes. Perioperative FBS was not a risk factor for poor visual and anatomic outcomes. Further research is necessary to further elucidate the association between blood pressure and visual recovery after vitrectomy surgery.

ABSTRACT BODY:

Purpose: To describe and compare macular neovascularization (MNV) associated with myopic macular degeneration (MMD) and age-related macular degeneration (AMD) using swept-source optical coherence tomography angiography (SS-OCTA).

Methods: Adult patients with documented MNV were recruited in this cross-sectional study and imaged using 6 x 6 mm angiograms on SS-OCTA. Several qualitative and quantitative features of MNV were assessed, including the MNV area and vessel density (VD). Descriptive statistics and linear regression analyses were carried out.

Results: A total of 75 eyes with MNV, including 30 eyes with MMD-MNV and 45 eyes with AMD-MNV, were considered in this study. Mean subjects' age in each group was 55 ± 19 years and 75 ± 8 years respectively. The MMD-MNV group exhibited three-fold smaller sized MNV ($p=0.001$), lower greatest linear dimension (GLD) ($p=0.009$) and greatest vascular caliber (GVC) ($p<0.001$) compared to AMD-MNVs, and had a higher prevalence of tree-in-bud pattern. Eyes with AMD showed a higher prevalence of type 1 MNVs with medusa pattern, and tended to have better defined margins with the presence of peripheral loops. There was no difference in the location of the MNV, the shape's regularity, the presence of a core vessel, a capillary fringe or a perilesional dark halo between both conditions (all $p>0.05$). MMD-MNV presented a significantly high proportion (59%) of non-discernable MNV on SS-OCTA in our cohort. After adjustment, decreased MNV area and increased VD were associated with the tree-in-bud pattern, whereas the diagnosis did not significantly influence those parameters.

Conclusions: This study is the first to describe and compare MMD-MNV and AMD-MNV using SS-OCTA, providing relevant insight on MNV secondary to MMD and AMD, and further validating OCTA as a powerful tool to detect and characterize MNV non-invasively.

TITLE: Richmond HRR and quality of life results in patients with color blindness wearing faded red tinted lenses

SESSION TITLE: Quality of Life Outcomes, Rehabilitation and Training Programs

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.A. Rodríguez, I. Domínguez Varela, M. Hernandez, Y. Macias, Oftalmologia, Instituto Tecnologico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO|

Commercial Relationships Disclosure: Luis Rodríguez: Commercial Relationship: Code N (No Commercial Relationship) | Irving Armando Domínguez Varela: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Yolanda Macias: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the effect of faded red filter lenses on the degree of severity of the Richmond HRR test scores in color blind people, the type of dyschromatopsia and its severity were classified, the results of a quality of life questionnaire was evaluated before and after the use of the glasses

Methods: Observational, descriptive and comparative study, in patients with color blindness in a Mexican population wearing faded chromatic lenses. Inclusion criteria comprised patients older than 6 years of age, who failed an Ishihara test, and had HRR Richmond tests performed before and after wearing the tinted lenses for more than 2 hours daily for 2 months.

Results: Fifty-one individuals with a diagnosis of dyschromatopsia were included. Fifty (98%) were men and 1 was female (2%). The mean age was 27.1 years (range 6-64y). When classifying the type of color blindness, the deutan group constituted 66.7% of the population, and 31.4% were classified as protans. Most subjects were classified as a severe grade of color blindness in (59.2%), followed by the moderate group (28.6%). The average percentage of incorrect answers in the Richmond HRR test prior to wearing the lenses was 45%, after using the lenses, an average percentage of incorrect answers of 26% was obtained. Subjects referred an improvement in the quality of life questionnaire scores from 13.74 points before using the glasses, to 9.61 points after wearing the tinted lenses.

Conclusions: Color blindness is a common condition affecting almost 1 in 12 men. This condition can have an effect on the quality of life these subjects because of the difficulty to perceive certain colors. In our study, almost all of the subjects were male, classified as severe deutans. Richmond HRR results improved with the use of the tinted lenses. After wearing the faded red tinted glasses the majority of subjects who were initially classified with a severe degree of dyschromatopsia, were classified with a mild degree of color blindness. These subjects also referred a subjective improvement in their quality of life. Further studies are needed to understand the effect of tinted glasses on the quality of life of subjects with color blindness.

TITLE: Surgical outcomes of scleral buckling for rhegmatogenous retinal detachment using the NGENUITY three-dimensional visualization system with a guarded light pipe

SESSION TITLE: Vitreoretinal Surgery

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Miller, J. Sokol, C.A. Ludwig, G. Baldwin, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: John Miller: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon;Code C (Consultant/Contractor):Allergan;Code C (Consultant/Contractor):Genentech;Code C (Consultant/Contractor):Carl Zeiss;Code C (Consultant/Contractor):Sunovion | Jared Sokol: Commercial Relationship: Code N (No Commercial Relationship) | Cassie Ludwig: Commercial Relationship: Code N (No Commercial Relationship) | Grace Baldwin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the surgical outcomes of traditional scleral buckling (SB) under indirect ophthalmoscopy (ID) for primary rhegmatogenous retinal detachment (RRD) repair to a new SB technique that utilizes the NGENUITY heads-up three-dimensional visualization system with a guarded light pipe (3DGLP).

Methods: A retrospective comparative study of 47 eyes that underwent SB for primary RRD by a single surgeon was performed. Electronic medical records of the ID group (n = 31) and the 3DGLP group (n = 16) were evaluated. In the 3DGLP group, the scleral buckle was attached to the eye in the traditional manor, but the retina was visualized with the NGENUITY 3D visualization system and a guarded light pipe. The guarded light pipe was created by sliding a trimmed Watzke-Allen sleeve onto the shaft of a light pipe as a guard to prevent insertion into the vitreous past the internal os of a single 25 or 27-gauge trocar cannula. The primary outcome of the study was single surgery anatomic success and secondary outcomes included final anatomic success, visual acuity, operative time, and intra and post-operative complications.

Results: The single surgery anatomic success rate was 87.0% in the ID group and 87.5% in the 3DGLP group ($p = 1.00$). The final anatomic success rate was 100% in both groups. The mean post-operative logMAR was 0.206 in the ID group and 0.339 in the 3DGLP group ($p = 0.4339$). The mean operative time was 110.3±24.9 minutes in the ID group and 101.0±16.4 minutes in the 3DGLP group ($p = 0.2533$). Among eyes that underwent subretinal fluid drainage, the operative time was significantly longer in the ID group compared to the 3DGLP group. There were no post-operative complications in the ID group and one episode of self-resolving vitreous hemorrhage in the 3DGLP group ($p = 0.3404$).

Conclusions: Compared to traditional SB surgery for the treatment of RRD, SB surgery utilizing NGENUITY three-dimensional visualization with a guarded light pipe results in similar anatomical, visual, and peri-operative outcomes and may result in a shorter surgical times with subretinal fluid drainage. This new technique allows for all participating surgeons, including trainees, to view critical procedural steps simultaneously while using the familiar light pipe tool for illumination.

TITLE: Müller glia-specific Notch signaling knockout mitigates reactive gliosis after ischemia-reperfusion injury

SESSION TITLE: Neuroprotection, blood flow and ischemia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.A. Gallo, G. Dvoriantchikova, H. Wang, A.H. Moeyersoms, K. Pino, D. Pelaez, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: Ryan Gallo: Commercial Relationship: Code N (No Commercial Relationship) | Galina Dvoriantchikova: Commercial Relationship: Code N (No Commercial Relationship) | Hua Wang: Commercial Relationship: Code N (No Commercial Relationship) | Acadia Moeyersoms: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Pino: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Pelaez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Notch signaling pathway has various roles during retinal development and is involved in the pathological changes that occur after retinal injury and disease. Notch signaling activation in Müller glia (MG) enhances reactive gliosis, neural death, and fibrosis after retinal injury. In mammals, four different Notch receptors (Notch1-4) have been identified. Yet, the specific roles of each receptor in the retina are not yet fully elucidated. We have generated transgenic animals to characterize the roles of Notch1 and Notch2 during MG gliosis. Given the activation of Notch1 signaling during retinal injury, we hypothesize that directly blocking Notch1 will mitigate reactive gliosis and subsequent neuropathic progression.

Methods: Retinal ischemia-reperfusion (IR) injury was induced in one eye of adult mice (8 to 12-weeks-old) by increasing intraocular pressure to 120 mmHg with normal saline for 1 hour. Ischemia was confirmed by fundus whitening. C57BL/6J mice were sacrificed and retinas isolated at various timepoints after injury for Western blot and staining. To determine how Notch signaling contributes to MG gliosis, we deleted Notch1 and Notch2 in MG via an inducible Cre/LoxP system driven by the MG-specific GLAST promoter (GLAST-CreERT; $Notch1^{fl/fl}$/$Notch2^{fl/fl}$). These transgenic mice received daily intraperitoneal injections of tamoxifen for 5 days prior to retinal IR injury. They were sacrificed 3 and 7 days after injury and their retinas were isolated for Western blot, staining, and RNA-Seq. Tamoxifen-treated GLAST-CreERT mice served as controls.

Results: Notch1 signaling is activated upon retinal IR injury in a time-dependent manner as confirmed by increases in Notch1 and cleaved Notch1 intracellular domain (NICD) expression on Western blot. MG-specific Notch1/2 knockout mitigates the gliotic response 7 days after IR injury as demonstrated by decreased GFAP expression on Western blot and immunofluorescence staining and reduced MG hypertrophy. RNA-Seq after IR injury on Notch1/2 KO and control mice retinas is ongoing. In addition, ChIP-Seq for the activated NICD on wild-type mice is underway to identify the genes Notch1 regulates directly during gliosis.

Conclusions: Notch1 signaling is activated after IR-mediated gliosis, and its direct blockage is a potential therapeutic strategy for retinal injury or disease.

ABSTRACT BODY:

Purpose: BRCA1-associated protein 1 (BAP1) is a tumor suppressor gene that is mutated in cancer, including uveal melanoma. Given that the loss of BAP1 is detected frequently in high-risk metastatic uveal melanoma cases, we sought to study molecular differences that could explain disease progression. In certain contexts, upregulation of cell-cell adhesion proteins is involved with collective migration and metastatic seeding of cancer cells.

Methods: We analyzed publicly available RNA sequencing data from 80 primary uveal melanoma cases in The Cancer Genome Atlas (TCGA), separated into BAP1 mutant (n=40) and wild-type (n=40) groups. We also analyzed single cell RNA sequencing data from BAP1 mutant and wild-type patient tumors, RNA sequencing from a panel of six BAP1 mutant (MM28, MP38, MP46, MP65, WM3618F and PDX4) and two BAP1 wild-type cell lines (92.1 and MM66), and RNA sequencing from a BAP1 mutant vs BAP1 re-expressing cell line (UM22). We used targeted knockdown of CDH1 and CADM1 to determine the functional role of cell adhesion molecules (CAMs) in BAP1 mutant uveal melanoma.

Results: We show that BAP1 loss in uveal melanoma patient samples is associated with an upregulated gene expression profile of multiple CAMs, including E-cadherin (CDH1), cell adhesion molecule 1 (CADM1), and syndecan-2 (SDC2). Similar findings were observed in uveal melanoma cell lines and single cell RNA sequencing data from patient samples. BAP1 re-expression in uveal melanoma cells reduced E-cadherin and CADM1 levels. Functionally, knockdown of E-cadherin decreased spheroid cluster formation and knockdown of CADM1 decreased growth of BAP1 mutant uveal melanoma cells.

Conclusions: Our findings demonstrate that BAP1 regulates the expression of CAMs which may regulate metastatic traits.

ABSTRACT BODY:

Purpose: Hypoxia-induced VEGF expression is a well-characterized disease mechanism that underlies ischemic retinopathies and requires stabilization of hypoxia-inducible factors (HIFs). However, less is known about HIF-independent hypoxia-sensitive pathways, which may alter the epigenetic landscape of hypoxic retinal cells and thereby promote the transcriptional activity of HIFs.

Methods: The oxygen-induced retinopathy (OIR) mouse model (75% O2 from P7-P12) was used to investigate histone modifications during acute retinal ischemia following hyperoxia exposure. Immunofluorescence (IF) and western blotting (WB) were performed at various timepoints in OIR mice (time post-hyperoxia exposure: 0 hours (h; baseline), 2h, 4h, 1 day (d), 3d, and 5d) to probe the spatiotemporal modifications that occur on histones following acute retinal ischemia, including H3K4me3, H3K9me3, H3K27me3, H3K36me2, and H3K36me3. The dynamicity of hypoxia-induced histone hypermethylation was examined using reoxygenation experiments in the OIR mouse model, where mice were removed from hyperoxia for 2h and then returned to hyperoxia (reoxygenation) for 2h or 4h. Lastly, IF, WB, and single-cell RNA-sequencing data (scRNA-seq) were used to examine the retina for expression of the hypoxia-sensitive histone demethylases, KDM5A and KDM6A.

Results: WB on whole retinal lysates showed that the hypoxia-sensitive histone demethylases, KDM5A and KDM6A, were strongly expressed in the mouse retina. IF and scRNA-seq showed that KDM5A and KDM6A were globally expressed in the retina, with the strongest expression in inner nuclear layer cells. WB on whole retinal lysates from OIR mice showed that H3K4me3 was induced as early as 2 hours following the onset of hypoxia, which mirrored the simultaneous stabilization of HIF1α. Reoxygenation experiments in OIR mice showed that the induction of H3K4me3 was rapidly reversible and that H3K4me3 levels returned to baseline within 2 hours of reoxygenation.

Conclusions: These findings reveal a novel, rapidly induced, and reversible hypoxia sensitive pathway in the ischemic retina that acts on histone modifications. H3K4me3 is a promoter-specific histone modification that influences transcription factor docking and thus, may play a role in instructing the genomic binding of HIFs during retinal ischemia.

ABSTRACT BODY:

Purpose: Allogeneic hematopoietic stem cell transplantation (HSCT) is an effective treatment for all array of haematological disorders, rendering improved disease prognosis and long-term survival rate. However, ocular graft-versus-host-disease (oGVHD) as a chronic complication of allogeneic HSCT affects patients' ocular health and their daily living. Vision-related quality of life (QOL) and its association with oGVHD were examined.

Methods: 134 patients who received allogeneic HSCT between year 2000 to 2010, and aged 18 or above at the time of transplant were recruited. oGVHD related ocular surface and adnexa changes were assessed by various ophthalmological examinations: Schirmer test without anaesthesia, measurement of tear meniscus height (TMH), non-invasive tear break-up time (NIBUT), conjunctival injection, corneal fluorescein staining, subconjunctival fibrosis (SCF) and meibomian gland dysfunction. Infrared meibographs were taken to assess meibomian gland dropout percentage by ImageJ software. Diagnosis of oGVHD was made based on both the National Institutes of Health (NIH) consensus criteria and the scoring system of International Chronic Ocular Graft-vs-Host-Disease Consensus Group (ICC). Ocular Surface Disease Index (OSDI) and National Eye Institute Visual Function Questionnaire-25 (NEI-VFQ25) were used for measurement of vision-related QOL.

Results: Of the 130 patients included in analysis (4 excluded as they had two or more allogeneic HSCT), 72 (55.3%) of them were male. Age at the year of BMT was 19-60 (s.d.= 10.9) and follow-up months since BMT was 133-262 months (s.d.= 39.5). With NIH dignosis criteria, 61.5% had oGVHD, with 43.1% having grade 1 severity and 18.5% having grade 2 severity. Diagnosis by ICC criteria showed 56.2% oGVHD in worst eye, with 27.7% having probable oGVHD and 28.5% having definite oGVHD. Mean MG atrophy in oGVHD patients by NIH criteria was 37.9% (s.d.=14.1) and non-oGVHD patients had 36.3% (s.d.=14.2) MG atrophy. OSDI in oGVHD and non-oGVHD patients by NIH criteria was 26.0 (s.d.=21.9) and 20.4 (s.d.=18.8) respectively.

Conclusions: Although MG atrophy did not show significant difference between oGVHD and non-oGVHD patients in this study, with oGVHD becoming more prevalent as allogenic HSCT advances, further studies are needed to correlate clinical findings and patient perceived QOL.

ABSTRACT BODY:

Purpose: To report the atypical presentation, clinical course, and visual outcomes associated with post-injection endophthalmitis (PIE) caused by Pseudomonas aeruginosa.

Methods: A detailed retrospective review was conducted of four cases of Pseudomonas aeruginosa PIE who presented from May – September, 2021 to different ophthalmology practices in Michigan.

Results: Four patients undergoing treatment for age-related macular degeneration (n=3) or diabetic macular edema (n=1) received right eye intravitreal injections of aflibercept (n=1), ranibizumab (n=1), bevacizumab (n=1), or dexamethasone implant (n=1) at two separate ophthalmic practices by three different providers on four separate dates. All patients were pseudophakic with a baseline vision of 20/20 to 20/50. Each patient subsequently developed rapid vision loss to hand motion (n=3) or light perception (n=1) and diagnosed with Pseudomonas aeruginosa endophthalmitis by aqueous fluid culture. Onset of endophthalmitis post-injection varied significantly with two patients presenting at the typical acute time frame (3 and 10 days post-injection) and the other two patients presenting during the subacute period (27 and 36 days post-injection). All patients received intravitreal vancomycin and ceftazidime and aqueous fluid biopsy on day of presentation, followed by a vitrectomy, vitreal biopsy, and repeat intravitreal antibiotics within 1-3 days after presentation. Despite all Pseudomonas strains being pansusceptible, these eyes continued to remain Pseudomonas culture positive on subsequent biopsies despite repeated intravitreal ceftazidime injections. There was a high incidence of post-vitrectomy choroidals and retinal detachment (n=3) which was associated with worse visual outcomes.

Conclusions: As far as the authors are aware, this is the first series of PIE caused by Pseudomonas aeruginosa. Important insights can be made into the atypical presentation and disease course to help guide future management. Unlike other cases of bacterial PIE, Pseudomonas persists within the eye despite intravitreal antibiotic injections with adequate coverage. In addition, a high rate of post-operative choroidals and retinal detachment were observed. Therefore, early vitrectomy, repeat antibiotic injections, and placement of silicone oil should be considered in these patients.

TITLE: Physiologically Based Dissolution Modeling for Topical Ophthalmic Suspensions

SESSION TITLE: Drug delivery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Jin, Sage Hill School, Newport Coast, California, UNITED STATES|H.J. Gukasyan, Department of Pharmacology and Pharmaceutical Sciences, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Clifford Jin: Commercial Relationship: Code N (No Commercial Relationship) | Hovhannes Gukasyan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The quality of an ophthalmic suspension is crucial to its clinical effectiveness and understanding formulation attributes is important for successful product development. This study aims to demonstrate the effect of physicochemical properties including solubility, pK_a (for ionizable molecules), and particle size with morphology/shape on in situ drug dissolution rate (e.g. release within tear following topical instillation). Such descriptors and relationships of simulated in vitro release tests (IVRT) can be used as input parameters for predictive optimization of sensitive product design parameters impacting drug absorption and disposition from complex topical ophthalmic suspensions.

Methods: DDDPlus™ and Ocular Compartmental Absorption & Transit (OCAT) v3, a module in GastroPlus™ (Simulations Plus, Inc.) were used to simulate drug dissolution (vs IVRT) and biodistribution (vs rabbit pharmacokinetics, PK) in aqueous humor (AH) and iris ciliary body (ICB) as target compartments. Measured or empirically estimated input parameters for drugs found in commercial topical ophthalmic suspensions were obtained from experimental literature. The simulation results were compared to IVRT, and then used for global optimization of physiologically based PK models. All referenced data were extracted from original publications using GetData Graph Digitizer®.

Results: DDDPlus™ simulations enabled fabrication of dissolution profiles similar to experimentally determined ones from IVRT. Between sets of dissolution predictions variations on mixing rate (e.g. blinking), USP simulated tear fluid (STF) composition, and molecular structure based vs. physicochemical property support files use were successfully evaluated. Without sensitive parameter identification and optimization DDDPlus™ tended to underpredict dissolution of studied drug particle examples. OCAT v3 simulated ocular exposures produced expected results and trends in rabbit AH and ICB from topical ophthalmic suspensions.

Conclusions: DDDPlus™ can serve as an initial assessment tool to build in vitro correlations with STF dissolution models, which can subsequently be relayed to OCAT v3 for ocular pharmacokinetic predictions. This is a novel tool being developed and promoted by the FDA for in silico approaches for establishment of bioequivalence in complex drug products, such as topical ophthalmic suspensions.

TITLE: Long Term Efficacy of Intraoperative Mitomycin-C in Novel Approach Small Incision Sub-tenon Ab-Interno XEN® Gel Stent Implantation

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.C. Roschke, Colorado Eye Institute, Colorado Springs, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Aaron Roschke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the long term efficacy of the intraoperative use of sub-tenon Mitomycin C in a novel approach sub-tenon ab-interno XEN® Gel Stent implantation IOP versus baseline intraocular pressure prior to surgery.

Methods: The study group consists of approximately 44 eyes with uncontrolled primary open-angle glaucoma without previous glaucoma surgery and with uncontrolled intraocular pressure, documented glaucoma progression, and/or intolerance to IOP-lowering therapy. All patients underwent Mitomycin C application via small incision sub-tenon Ab-Interno XEN® Gel Stent Implantation as a stand-alone procedure by a single surgeon. Recovery included tapering postoperative steroid drops through 4 weeks following surgery and adjusting topical glaucoma drops based on intended target intraocular pressure. Postoperative visits were conducted for all patients at regular intervals through 12 months. Surgical outcome tracking assessed through IOP measurement via calibrated Goldmann Applanation Tonometry by a single surgeon.

Results: Of the 44 subject eyes at 6 month interval, 100% of the population had IOP below 17mmHg, 91% of the population 15mmHg or below, and 55% of the patient population of 12mmHg or lower. The mean decrease in topical glaucoma medications was 1.95 ± 1.31 at 6 month postoperative period. The mean IOP was 13.13 ± 1.64 ($p=0.003$) at 6 month postoperative period. At the 12 month postoperative interval, 3 subjects were lost to follow-up, 90.2% of the patient population had an IOP 17mmHg or lower, 70.7% of the patient population 15mmHg or lower, and 51.2% of the patient population 13mmHg or lower. The mean IOP after the 12 month postoperative period was 14.07mmHg ± 3.80.

Conclusions: Application of Mitomycin C in a novel approach sub-tenon ab-interno XEN® Gel Stent implantation appears to demonstrate high efficacy for the reduction in intraocular pressure (IOP) in patients with uncontrolled primary open-angle glaucoma.

TITLE: Structure and stability of domain-swapped mutant γ-crystallins: implications for lens cataract and βγ-crystallin evolution

SESSION TITLE: Molecular and Biochemical Mechanisms of Ocular Disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.C. Thorn, E. Serebryany, E. Shakhnovich, Harvard University Faculty of Arts and Sciences, Cambridge, Massachusetts, UNITED STATES|G. Birrane, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, Massachusetts, UNITED STATES|A. Kaya, Argonne National Laboratory Advanced Photon Source, Lemont, Illinois, UNITED STATES|

Commercial Relationships Disclosure: David Thorn: Commercial Relationship: Code N (No Commercial Relationship) | Eugene Serebryany: Commercial Relationship: Code N (No Commercial Relationship) | Gabriel Birrane: Commercial Relationship: Code N (No Commercial Relationship) | Ali Kaya: Commercial Relationship: Code N (No Commercial Relationship) | Eugene Shakhnovich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vertebrate βγ-crystallins adopt two homologous domains connected via a linking peptide which is considered a key determinant of their tertiary and quaternary arrangements. In vitro, γ-crystallins are monomeric whereas β-crystallins form mainly dimers that are thought to associate further via domain-swapping to form larger oligomers. This study aims to better understand the oligomeric preferences of βγ-crystallins.

Methods: The propensity to form domain-swapped dimers in mutant γ-crystallins was predicted with AlphaFold Multimer and initially assessed by Superdex-75 column size-exclusion chromatography. The dimeric structure was determined by X-ray crystallography. Aggregation propensity was assessed by turbidimetry. Thermal stability was measured by circular dichroism and differential scanning calorimetry.

Results: Several γ-crystallin mutants adopted non-covalently associated dimers in solution under both reducing and non-reducing conditions. The crystal structure of one select mutant shows a domain-swapped dimer, distinct from the compact ‘face en face’ dimeric structure of β-crystallin in solution. The domain structures show no structural perturbation and the conserved interface between the N- and C-terminal domains is preserved. The domain-swapped dimers of γ-crystallin are not markedly aggregation-prone at physiological temperature relative to their wildtype monomeric counterparts; however, they exhibit reduced thermodynamic stability.

Conclusions: Domain-swapped dimers of vertebrate βγ-crystallins are less stable and are unfavorable in an aging lens where the risk of protein misfolding and aggregation is pronounced due to cumulative post-translational modifications. The long-lived crystallin proteins have therefore been engineered to avoid domain-swapped dimerization in order to retain their soluble, folded conformations throughout adulthood and avoid diseases of the lens such as cataract.

ABSTRACT BODY:

Purpose: To assess if specific findings gathered during an examination of patients with a known angle closure diagnosis (probands) could better determine the risk of angle closure in the patient's sibling.

Methods: Patients 30 years and older with suspect primary angle closure (PACS) or primary angle closure/primary angle closure glaucoma (PAC/G) seen at the Aravind Eye Hospital in Pondicherry, Tamil Nadu, and a biological sibling above age 30 years, were recruited as 'probands' and 'siblings' (n=346 pairs). Demographics, ocular history, and an ophthalmic examination with Anterior Segment Optical Coherence Tomography (ASOCT) were obtained. Siblings were classified as having open angles (OA), PACS, or PAC/G per ISGEO criteria. Models were created to analyze the contribution of specific proband factors in predicting sibling angle closure diagnosis.

Results: When predicting (1) any sibling angle closure (PACS or PAC/G) vs. open angles, (2) sibling PAC/G vs PACS or OA, or (3) PAC/G vs. PACS amongst siblings with angle closure, models incorporating proband ASOCT data outperformed models including proband diagnosis alone or proband diagnosis plus demographic (age/gender) and exam metrics (gonioscopy, optic nerve exam, visual acuity, and intraocular pressure). For example, in the prediction of PAC/G vs. PACS amongst siblings with angle closure, the model using only proband diagnosis had the lowest explained variability (0.64%). Adding proband demographics and ocular exam metrics improved model accuracy to a limited extent (1.99% of variability explained), while adding ASOCT Metrics created a significant improvement (17% of variability explained, $p<.0001$ vs other models). The model incorporating ASOCT metrics resulted in the lowest Bayesian Information Criterion (101.9 vs. 123.6 for the diagnosis-only model and 119.7 for the diagnosis + demographics + exam metrics model).

Conclusions: Utilizing ASOCT information from angle closure patients can help better predict sibling angle closure status, leading to more efficient and cost-effective screening of family members.

TITLE: Utility of Intraoperative Optical Coherence Tomography In Optimizing Air Fill for Endothelial Keratoplasty

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Berkowitz, A. Ramaprasad, M. Tseng, S. Basti, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Carla Berkowitz: Commercial Relationship: Code N (No Commercial Relationship) | Abhijit Ramaprasad: Commercial Relationship: Code N (No Commercial Relationship) | Michael Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Surendra Basti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A full air fill and sufficiently high intraocular pressure (IOP) are crucial to ensure optimal graft adhesion during endothelial keratoplasty. While air fill and IOP can be approximated on the operating table, it is difficult to quantify if the air fill will provide an adequate IOP. The purpose of this study is to evaluate how the air fill in the anterior chamber anterior chamber (AC) correlates with IOP, AC depth, and the iris configuration.

Methods: Cadaveric human eyes were mounted on a microscope with intraoperative optical coherence tomography (OCT). Inclusion criteria for the eyes included pseudophakia and harvest time within 48-72 hours. Three categories were used: baseline, an air fill that just spanned limbus to limbus (“limbus to limbus”), and an air fill that maximally filled the entire AC (“max fill”). IOP was measured by taking the average of 3 Tono-pen (Reichert, Buffalo, New York) measurements. OCT images were obtained in the operating room and analyzed using ImageJ software. ImageJ was used to measure the distance from the posterior cornea to the anterior iris to determine AC depth, and to measure the angle between the iris and the cornea to determine iris configuration.

Results: Preliminary data has shown that at baseline the IOP was 14.33, AC depth was 3.067, and an irido-corneal angle of 37.33°. Limbus to limbus fill had an IOP of 14.33, an AC depth of 2.968, and an irido-corneal angle of 36.25°. Max fill had an IOP of 17.33, an AC depth of 3.37, and an irido-corneal angle of 44.09°. Finalized data will be based on a total of 10 eyes to power this study, assuming an 80% power, a p-value of <0.05, an R-squared of 0.50, and a single variable model.

Conclusions: Early data has indicated a correlation of IOP with AC depth as perceived on intraoperative OCT. In addition, while an air bubble may appear to fill the AC, as demonstrated by the “limbus to limbus” category, it’s IOP may not be sufficiently high to optimize graft adherence. Finally, a concave iris contour on OCT may be a reliable surrogate to suggest an adequate anterior chamber fill.

TITLE: Estimating Pedestrian Detection with peripheral prisms in Homonymous Hemianopia

SESSION TITLE: Mobility, Reading and Driving with Vision Impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Manda, A.D. Hwang, J. Jung, E. Peli, Opthalmology, Massachusetts General Hospital, Boston, Massachusetts, UNITED STATES|N.M. Kurukuti, Biomedical Engineering, Northwestern University, Evanston, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Sailaja Manda: Commercial Relationship: Code N (No Commercial Relationship) | Nish Kurukuti: Commercial Relationship: Code N (No Commercial Relationship) | Alex Hwang: Commercial Relationship: Code N (No Commercial Relationship) | Jae-Hyun Jung: Commercial Relationship: Code N (No Commercial Relationship) | Eli Peli: Commercial Relationship(s);Code P (Patent):Chadwick Optical

ABSTRACT BODY:

Purpose: Fresnel(F, 57PD) and Multiperiscopic(M, 100PD) prisms are peripheral prisms designed to expand the visual field for persons with Homonymous Hemianopia (HH). Prism segments are placed above(U) and below(L) the pupil in a horizontal(H) or oblique(O) configuration. We constructed a mathematic model to simulate pedestrians walking toward a patient wearing any combination(U/L/Both(U&L)) of (F/M) prisms to compare detection rates and estimate if wearing single prism(U/L) is as good as both(U&L).

Methods: The dataset simulated 6-second events of a patient wearing F/M looking straight ahead without eye movement and walking toward a collision point. A pedestrian approached at 0°-90° to this point (at 1° intervals). We modelled 6 pedestrian forms based on physical anthropometry measurements. Each form used 80 data-points to model patient and pedestrian attributes such as walking speed, height, torso, arm/leg width and span. A pedestrian was categorized detected if the height/width of the pedestrian's image within the prism was >3°(based on experiment data collected from 4 HH patients). Detection rates were computed for 540 events per HH model wearing a U/L/U&L prism combination of F/M prisms. Differences in detection rates were analyzed using a 2(F/M) x 2(H/O) x 3 (U/L/U&L) ANOVA.

Results: The detection rate with any prism(F:0.40±0.38, M:0.62±0.32) was better than without prisms(0.05±0.2). There were significant main effects(all ps<0.001) of the type of prism design(F vs M), configuration(H: 0.62±0.4, O: 0.37±0.27) and number of segments(U:0.15±0.03, L: 0.67±0.33, U&L:0.71±0.33). All interactions between these variables were significant(all ps<0.001). The LH configuration(LHF:0.82±0.01, LHM:1) had the best detection rates and these were not significantly different from three of the U&L prisms performance(U&L HF:0.824±0.01, U&L HM:1±0, U&L OM: 0.782±0.02).

Conclusions: A mathematic model was used to simulate if a single prism supported detection as well as dual peripheral prism configurations in the absence of observer head tilt or eye movement. Use of a single prism configuration would provide reduced cost and better cosmesis for patients. Mathematic modeling to estimate detection can combine real world physical measurements with theoretical prism expansion calculation. Further analyses with head and gaze shift modelling could be a useful tool to support design of peripheral prisms and aid clinical decision making.

TITLE: Patient satisfaction with teleophthalmology in ocular oncology.

SESSION TITLE: Eyecare delivery and economics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Campbell, T. Crump, E. Weis, University of Calgary, Calgary, Alberta, CANADA|E. Weis, University of Alberta, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure: Paige Campbell: Commercial Relationship: Code N (No Commercial Relationship) | Trafford Crump: Commercial Relationship: Code N (No Commercial Relationship) | Ezekiel Weis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Teleophthalmology decreases barriers to accessing highly specialized care, such as ocular oncology. However, there is a dearth of research into patients' perceptions of having care delivered through this modality. The purpose of this study is to evaluate patients' satisfaction with a teleophthalmology program for ocular oncology and whether it addressed their healthcare needs.

Methods: The teleophthalmology program includes diagnostic imaging, remote physician assessment, and a follow-up phone call from a member of the healthcare team to relay results to patients. Patients who had received care from this program were contacted and asked to participate in this study. Those that agreed were surveyed using an adapted version of the Telehealth Satisfaction Scale (TeSS) and four open-ended questions pertaining to their healthcare needs. The TeSS is scored out 32, with higher scores indicating greater satisfaction.

Results: To-date, 15 of patients were contacted, and 13 agreed to be surveyed (response rate = 87%). On average, participants had received care from the teleophthalmology program 3 to 4 weeks from the time they were surveyed. The median TeSS score was 32 (SD = 1.57), ranging from 28 to 32, indicating high satisfaction with the program. 44% (n = 4) of participants lived in a rural community, where they would otherwise have had to travel between 27 to 110 kilometers to receive specialized ophthalmic care in-person. Overall, patients responded positively to open-ended questions stating the convenience and lack of waiting times was preferred to in-person appointments. Four patients advocated for further use of technology in additional modalities as they appreciated regular communication with their healthcare providers.

Conclusions: The analysis demonstrates that patients of an ocular oncology clinic are highly satisfied with a teleophthalmology program. The delivery of this kind of specialized care mitigates the access barriers to rural patients while still meeting patients' needs and perceptions.

ABSTRACT BODY:

Purpose: This study aims to characterize anatomical and functional changes in the ocular surface after allogeneic hematopoietic stem cell transplantation in the absence of GVHD.

Methods: A total of 8 eyes of 4 patients with hematologic malignancies requiring HSCT were prospectively recruited for this pilot study. All patients underwent a full ophthalmic examination before and 3 months after transplantation. Examinations performed on all subjects included OSDI survey, tear matrix metalloproteinase (MMP)-9 test, tear break-up time (TBUT), corneal fluorescein staining (Oxford scale), lower lid meibomian gland dysfunction score and lower lid meibography. In addition, in vivo confocal microscopy (IVCM) imaging of the central cornea was used to evaluate morphological changes of the corneal epithelial layers, corneal nerves and presence of dendritic cells (DCs).

Results: The mean age of patients was 42.75 ± 19.8 years, and mean follow-up was 91.25 ± 25.7 days after allo-HSCT. Four eyes of two patients patients exhibited positive results for MMP-9 test after transpantation despite all 8 eyes having tested negative for MMP-9 at baseline.

In the early-stage post transplantation, no statistically significant differences were found in the following variables when compared to baseline: OSDI score (P=0.067), TBUT (P=0.181), Schirmer's test (P=0.059), corneal fluorescein staining score (P=0.085), meiboscore (P=0.142) and meibography (P=0.5).

IVCM images obtained from 4 eyes of 2 patients at baseline and post allo-HSCT were analyzed. There were no significant differences in epithelial wing cell density (P=0.281), epithelial basal cell density (P=0.089), subbasal nerve density (P = 0.468) and DC density (P=0.093).

Conclusions: In our study, significant changes were not observed in the ocular surface parameters prior to and after all-HSCT. However, MMP-9 was detected in tears of 50% of eyes after transplantation in the absence of any ocular surface symptoms or clinical changes.

Although many patients are asymptomatic, severe dry eyes is a common finding after allo-HSCT in the context of oGVHD. The risk of oGVHD development is elevated in the first year of transplant, and there is substantial evidence that the ocular surface and meibomian glands are damaged in patients with this condition. Further study is required to determine what role, if any, the presence of MMP-9 plays in early detection of oGVHD.

TITLE: TIME-COURSE ANALYSIS OF HUMAN TRABECULAR MESHWORK SINGLE CELL CONTRACTION AFTER A 5-DAY DEXAMETHASONE TREATMENT

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.U. Sanchez, J.J. Zheng, C. Zhang, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Luis Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Jie Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Chi Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glucocorticoids, such as dexamethasone (Dex), are speculated to alter the contractile properties of human trabecular meshwork (HTM) cells. However, there are no definitive studies showing that dexamethasone treatment modulates the contractile forces exerted by HTM cells in vitro. Because cellular contraction is a dynamic process, it is important to quantify changes in contractile force generation over time. Additionally, observed heterogeneity in primary HTM cell cultures call for single cell contraction measurements.

Methods: In order to measure HTM cell contraction at the single cell level, primary HTM cells from 4 different donors were cultured for 5 days in the presence of DMSO vehicle, or 0.1μM Dex. After 5 days, primary HTM cells from each condition were harvested, dissociated to single cells, and seeded into the wells of the fluorescently labeled elastomeric contractible surfaces (FLECS) assay for single cell contraction measurements. Data were collected every 2 hours over a period of 16 hours and analyzed using computational algorithms.

Results: Interestingly, a single large population of weakly contractile cells and smaller subpopulations of strongly contractile cells were identified across both conditions. The strongly contractile subpopulations remained smaller compared to the single weakly contractile cell population throughout the course of 16 hrs. Furthermore, the strongly contractile cell subpopulations became increasingly prominent in the DMSO vehicle condition throughout the course of 16 hrs. Dex treated cells also displayed small subpopulations of strongly contractile cells. However, these subpopulations were smaller compared to DMSO vehicle, and remained mostly unchanged throughout the course of 16 hrs.

Conclusions:

Based on our findings, Dex treatment appeared to reduce the ability of a population of primary HTM cells to exert strong contractile forces.

TITLE: Antigen-driven immune responses distinguish uveitis subtypes.

SESSION TITLE: Uveitis: Human and Murine Experimental Medicine Studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Hassman, Department of Ophthalmology and Visual Science, Washington University in St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Lynn Hassman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Non-infectious uveitis is a heterogeneous group of blinding ocular inflammatory diseases whose pathophysiologic mechanisms are poorly understood. This results in empiric treatments that are ineffective for many patients. We therefore set out to identify immunologic mechanisms that would differentiate uveitis subtypes and reveal therapeutic targets.

Methods: We performed single-cell V(D)J sequencing to identify clonally expanded lymphocytes, an indication of antigen-driven immune responses, in parallel with single-cell RNA sequencing in order 1)identify antigen-expanded lymphocytes and 2) characterize the gene expression of aqueous fluid and peripheral blood immune cells from 18 patients with diverse types of uveitis.

Results: We identified clonal CD4 T cell expansion in aqueous samples from a subset of patients with uveitis, suggesting that these ocular immune cells had responded to an antigen. Furthermore, we found that patients with robust CD4 clonal expansion tended to have granulomatous features and prolonged disease courses. Furthermore, these patients' CD4 T cells were enriched in expression of genes associated with the effector memory cell state, a group of antigen-experienced T cells that drive chronic or recurrent inflammatory disease. These patients also had more type 1 conventional dendritic cells (DC1s) enriched in expression of genes required for activating T effector memory cells, and fewer type 2 conventional dendritic cells (DC2s).

Conclusions: This suggests that antigen-driven immune responses may be a distinguishing feature in uveitis patients with granulomatous features and prolonged disease courses. Furthermore, the correlation between increased frequencies of DC1s and CD4 clonal expansion suggests that DC1s may activate CD4 T effector memory cells to drive chronic granulomatous uveitis.

ABSTRACT BODY:

Purpose: To assess epithelial cell remodeling after myopic laser vision correction with a new femtosecond laser for the correction of myopia and astigmatism through intrastromal lenticule removal procedure.

Methods: A prospective clinical study in myopic subjects ≥18 years is ongoing. 48 eyes of 24 myopic subjects were treated binocularly at 1 site for vision correction using a new femtosecond laser. Mean pre-operative Manifest Refraction Spherical Equivalent (MRSE) was -4.04 D and ranged from -2.00 D to -6.25 D (SD: 1.17 D). A lenticule removal procedure was used. The RTVue anterior segment Pachymetry + Cpwr scan (SW Ver. 6.11.0.12) was used to generate epithelial thickness maps comprised of 17 sectors over a 6 mm diameter circle. One central 2 mm diameter circular sector, 8 sectors within an annulus 2-5 mm diameter (ring-1), and 8 sectors within an annulus 5-6 mm diameter (ring-2). ANOVA with Tukey pairwise comparison was used to evaluate change in total epithelial thickness and change in superior versus inferior thickness from pre-operatively (44 eyes) to 1-day (42 eyes), 1-week (44 eyes), 1-mo (44 eyes), and 3-mo (17 eyes) post-operatively. A correlation between pre-operative MRSE and change in epithelial thickness was also evaluated.

Results: No significant change in epithelial thickness was found in the central sector at all time points. In ring-1, there was variability with significant thickening (1.47 μm) from pre-op to 1-day post-op followed by a significant thinning of 1.41 μm at 1-week and then continuous thickening at 1- and 3-mo post-op of 2.37 and 0.22 μm, respectively ($p = 0.0001$). In ring-2 there was a continuous thickening at 1- and 3-mo post-op of 1.47 and 1.08 μm, respectively ($p = 0.0001$). No significant change was observed between the superior vs. inferior sectors, and no correlation was found between pre-op MRSE and change in epithelial thickness ($R^2 = 0.07, 0.05$ for 1 and 3-mo post-op).

Conclusions: Significant change in epithelial thickness after lenticule removal with the new femtosecond laser was observed in rings 1 and 2. This thickening may be attributed to epithelial remodeling and is apparent at 1- and 3-mo post-op. No difference between superior and inferior change in thickness implies no effect of the lenticule entry cut on remodeling.

ABSTRACT BODY:

Purpose: To evaluate choroidal blood vessels in retinal degenerative diseases using a novel biomarker calculated from a three-dimensional (3D) model of the choroid.

Methods: The subjects were crystallin retinopathy (CR) 6 eyes of 4 patients, retinitis pigmentosa (RP) 23 eyes of 13 patients. Controls were healthy eyes with no age difference 51 cases 51 eyes. Swept Source optical interference tomography A 3D model was created from the (OCT) image (6 x 6 mm) based on the previous report. The foveal choroid thickness (CT) was measured with an OCT tomographic image. From the 3D model, choroidal blood vessel volume (CVV), blood vessel surface area/volume ratio (S / V) as an index of the size of blood vessel structure, blood vessel diameter index (blood vessel diameter index) and blood vessel length per unit volume (blood vessel length index)) was calculated.

Results: The average value of CT (μm), CVV (mm^3), S / V (mm^{-1}), vessel diameter index (mm), vessel length index (mm^{-1}) is 117, 0.42, 124, 0.031, 62 for CR, 164, 0.68, 94, 0.042, 53 for RP, and 255, 1.27, 86, 0.042, 49 for control. In CR and RP, CT, CVV, and blood vessel diameter index were smaller and S / V was larger than in the control (all $P < 0.05$). The vessel length index was large in CR ($P = 0.043$) and was not different from the control in RP ($P = 0.162$).

Conclusions: Both CR and RP have smaller CT and CVV than healthy eyes. From the decrease in the blood vessel diameter index, it is considered that the decrease in the blood vessel diameter has an effect on both diseases. CR has a high vessel length index, and the choroidal parenchyma may be more severely impaired. New biomarkers using 3D models can evaluate choroidal vascular morphology.

TITLE: Lamination of the outer plexiform layer in dominant Wolfram disease
SESSION TITLE: Genetic variants in human ocular disease
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: S. Hull, A.L. Vincent, Ophthalmology, The University of Auckland Faculty of Medical and Health Sciences, Auckland, Auckland, NEW ZEALAND|
Commercial Relationships Disclosure: Sarah Hull: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Vincent: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Heterozygous variants in WFS1 are associated with a Wolfram- like syndrome characterised by sensorineural hearing loss, optic atrophy and diabetes mellitus. A previous study described outer plexiform layer (OPL) lamination in dominant WFS1 disease. In this report two further patients are described.
Methods: This was a retrospective case study of two probands from two families with detailed clinical phenotyping including ophthalmic examination, optic nerve and retinal imaging, and neuroimaging. Molecular investigations included targeted Sanger sequencing and next generation gene panel sequencing.
Results: Two female patients with a background of congenital, severe sensorineural hearing loss, were incidentally found aged 10 years and 16 years to have optic disc pallor, with slightly reduced visual acuity (0.2-0.3 logMAR) and reduced color vision. Optical coherence tomography (OCT) of the nerve fiber layer identified severe generalised thinning. OCT of the macula demonstrated a linear splitting abnormality of the OPL within the central macula. Neuroimaging confirmed no intracranial cause of optic neuropathy.

In both probands, heterozygous variants were found in WFS1, specifically c.937T>C (p.His313Tyr) and c.2590G>A (p.Glu864Lys), both previously reported in affected patients. After identification of the optic neuropathy, diabetic screening was performed confirming diabetes mellitus in one proband.
Conclusions: In optic atrophy, OCT macula may reveal a pathognomonic OPL lamination that is associated with dominant WFS1 variants.

ABSTRACT BODY:

Purpose: To compare the visual performance of a non-tinted monofocal intraocular lens (IOL) (ZCB00) and a yellow-tinted monofocal IOL (ZCB00V) of the same material and basic design.

Methods: We evaluated postoperative parameters at 10 weeks after the last surgery in cataract patients who underwent bilateral ZCB00 or ZCB00V implantation from January 4, 2011, to November 19, 2020, with the right and left lenses implanted within 3 months of each other. The study enrolled 2278 eyes of 1139 patients. A linear mixed-effects model using data for both eyes, with strict adjustments for sex, age, subjective refraction spherical equivalent, subjective refraction cylinder, corneal astigmatism, axial length, corneal higher-order aberrations, and pupil diameter, ensured statistical validity.

Results: Contrast sensitivity with glare (6.3/4.0/0.7 degrees) were significantly better in the yellow-tinted group ($p<0.00068$, Wald test), and contrast sensitivity (4.0/2.5/1.6 degrees), contrast sensitivity with glare (2.5/1.6/1.0 degrees), the 25-item National Eye Institute Visual Function Questionnaire (VFQ-25) score for general health, and near spectacle independence were likely better in the yellow-tinted group ($p<0.05$, Wald test). Uncorrected intermediate/near visual acuity (UIVA/UNVA), corrected near visual acuity (CNVA), higher-order aberration (internal, scaled to a pupil size of 6 mm) (WF_6_post_I_Trefoil), the VFQ-25 scores for Role_Limitation, Mental_Health, Social_Function, Distance_Vision, Color_Vision, were likely better in the non-tinted group ($p<0.05$, Wald test).

Conclusions: The two IOL groups had different characteristics in terms of UIVA/UNVA/CNVA, contrast sensitivity, contrast sensitivity with glare, the VFQ-25 scores, higher-order aberration, and near spectacle independence.

Cheung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the association between pachydrusen and changes in fundus autofluorescence (FAF) in eyes with central serous chorioretinopathy (CSC) and polypoidal choroidal vasculopathy (PCV).

Methods: Retrospective review of 75 eyes with CSC and 33 eyes with PCV. Color fundus photo, FAF and optical coherence tomography (OCT) were evaluated to assess for pachydrusen, changes in FAF and OCT subfoveal choroidal thickness (SFCT).

Results: Pachydrusen were found in 18.7% of CSC eyes and 63.6% of PCV eyes. The mean age of patients with eyes having pachydrusen was significantly older than those without pachydrusen in both CSC and PCV ($P<0.001$ and $P=0.003$, respectively). No significant difference was found in the mean SFCT in both CSC and PCV eyes with or without pachydrusen. More extensive area of FAF abnormalities was found to be associated with eyes with pachydrusen ($P=0.041$).

Conclusions: Pachydrusen are more prevalent in eyes with PCV than CSC. Pachydrusen are associated with increasing age and more extensive retinal pigment epithelial abnormalities as shown by the FAF changes.

ABSTRACT BODY:

Purpose: To investigate the changes of the vitreoretinal interface as seen on multimodal adaptive optics imaging of eyes with uveitis.

Methods: Four eyes (4 patients) affected by fovea-attached (subtype 1A) or fovea sparing epiretinal membranes (ERM) on spectral domain optical coherence tomography (SD-OCT) or visible internal limiting membrane (ILM) on Infrared fundus imaging were recruited in this pilot study.

The microstructure of the vitreoretinal interface was imaged using flood-illumination adaptive optics (FIAO) and images were compared to the cross-sectional SD-OCT data.

Two eyes from 2 additional patients with Gunn's dots identified by FIAO had their FIAO images compared with the microstructures seen associated with ILM.

Results: Adaptive optics images revealed multiple abnormalities of the vitreoretinal interface, such as deep linear striae in ERM, and hyperreflective microstructures at the location of ERMs (picture 1) and ILMs.

The Gunn's dots were morphologically different from the hyperreflective microstructures or spots associated with the ILM and ERM.

Conclusions: FIAO imaging can identify specific patterns associated with ERMs and ILMs.

FIAO imaging of the vitreomacular interface and its correlation to FIOA imaging of outer retinal structures to discerne structural alterations can be valuable to understand the cause of significant macular dysfunction associated to ERM.

TITLE: Patients diagnosed with autosomal dominant macular or pattern dystrophy who harbor the mutation p.Pro210Arg in PRPH2 have clinical abnormalities in both rod and cone photoreceptors

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.D. Bennett, N. Al Kadhem, Ophthalmology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|D.G. Birch, Retina Foundation of the Southwest, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Lea Bennett: Commercial Relationship: Code N (No Commercial Relationship) | David Birch: Commercial Relationship: Code N (No Commercial Relationship) | Niyaf Al Kadhem: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mutations in PRPH2 are among the leading genetic causes of inherited retinal diseases (IRD). More than 200 different mutations in PRPH2 have been associated with multiple subtypes of IRD including retinitis pigmentosa and cone or macular diseases. The molecular mechanism associated with the mutation p.Pro210Arg (P210R) in PRPH2 has not been evaluated and little is known about the clinical presentation of patients with this particular genetic defect. The purpose of this research was to understand how this mutation affects visual function and retinal structure as well as gain insight into the mechanism driving the clinical features observed in these patients.

Methods: Eleven patients from seven families had clinical assessments including best corrected visual acuity (BCVA), static (spot size V) perimetry (Octopus 900) and dark-adapted chromatic (DAC; Medmont; spot size V) perimetry. Images were acquired with the Optos ultra-wide field camera and spectral-domain optical coherence tomography (SD-OCT).

Results: Patients who were previously determined to harbor the P210R mutation in PRPH2 had BCVA (Snellen) that ranged from 20/15 to 20/80. Perimetry exams showed an overall reduction in sensitivity. Scotomas were identified that corresponded to atrophic lesions on the retina. Imaging revealed drusen, hyper-fluorescent flecks, migrating RPE, interruptions in the inner/outer-segment junction, and foveal sparing.

Conclusions: Rod and cone sensitivity was decreased in subjects with the P210R mutation in PRPH2. However absolute vision loss occurred within the macula and likely secondary to drusen formation. This suggests that although rod and cone photoreceptors are dependent on PRPH2, preventing blindness in this specific subgroup of patients should involve therapeutics to impede drusen formation.

ABSTRACT BODY:

Purpose: The eyePlate glaucoma drainage implant (eyePlate, Rheon Medical SA) is a novel non-valved drainage device constructed entirely out of medical grade silicone. This study evaluates the 6-month efficacy and safety of the eyePlate-300 implant in cases of uncontrolled glaucoma. To our knowledge this is the first report of this novel glaucoma drainage implant device.

Methods: A retrospective, non-comparative study of 16 consecutive eyes treated with the eyePlate-300 glaucoma drainage implant at the Western Eye Hospital, London between March 2020 and April 2021 was performed.The patients were followed up for 6 months. For all patients, care was overseen by the same glaucoma consultant who performed all the surgeries under local anaesthesia. The Kolmogorov-Smirnov and Shapiro-Wilk tests established normality of results. The paired t-test was used to assess statistical significance of the results.

Results: A total of 15 patients (16 eyes) were included. The mean age was 59.7 (15.8) years. The most common diagnosis was primary open angle glaucoma (37.5%). Previous procedures included trabeculectomy (31.25%), micropulse diode laser trabeculoplasty (56.25%), iStent (12.5%) and cyclodiode laser (12.5%). Mean pre-treatment IOP was 31.5 (mmHg. There was a significant reduction ($p<0.05$) in IOP at 1 month to 11.8 (4.2) mmHg (62.6% reduction), at 3 months to 16.25 (2.3) mmHg (51.6% reduction) and at 6 months to 15.4 (2.2) mmHg (51.1% reduction). The requirement of topical treatment significantly reduced ($p<0.0.5$) from a baseline of 3.44 (1.09), to 2.06 (0.42) at 1 month, 2.0 (0.47) at 3 months and 2 (0.46) at 6 months. There was no statistically significant drop in visual acuity or increase in central retinal thickness found. Two patients (12.5%) experienced prolonged uveitis requiring extended steroid treatment for resolution. Three patients (18.75%) had post-op hypotony with choroidal effusions but showed an improved VA at 6 months. None of the patients required any further surgery.

Conclusions: The above results have shown the eyePlate-300 to be significantly effective in reducing IOP and need for topical treatment in patients with refractory glaucoma within a 6-month period following surgery. Further long-term data is needed to confirm efficacy and comparability to current commonly used procedures.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) cells have been shown to be primary affected in age-related macular degeneration (AMD). We report here the results of transscleral optical imaging (TOI) in AMD patients. This image modality has been developed for in vivo visualization of RPE cellular structure in human retina.

Methods: 25 non-neovascular AMD cases with clear optic media and good fixation were recruited for TOI, associated with conventional imaging: spectral domain optical coherence tomography (OCT), autofluorescence, color and infrared fundus imaging. Five zones of 5.04x5.04 degrees were acquired with TOI: one was foveal, four were localized in the macular quadrants at 3.8° eccentricity. The resulting TOI images were optimized for contrast and confronted with information from conventional multimodal imaging.

Results: Included were 31 eyes of 25 AMD patients (mean age 71.8 years, 56% females). Prominent features on the TOI images were the reticular pattern of the choriocapillaris, particularly well contrasted on areas of geographic atrophy and RPE hypopigmentation, and the presence of additional dark spots irregularly distributed (Fig. 1C). These dark spots, with size varying from 1 time to approximately 15 times the mean RPE cell size, were located on the low reflectance areas of the choriocapillaris, and particularly present in the border area around atrophic zones and in areas of visible RPE changes. A subgroup of these cells, showing a bright halo around them, correlated well with drusenoid deformation of the RPE line on SD-OCT. Dark spots were particularly frequent in eyes with reticular pseudodrusen. Drusen were also observed in a particular pattern of hyporeflective center with hyperreflective edges. An example of TOI images is given in the figure, including correlation with clinical fundus autofluoresence (FIG 1A) and OCT (FIG 1B).

Conclusions: TOI performed in 25 AMD patients revealed different patterns of altered tissue in the RPE layer. Upon confirmation of these results, TOI might become a relevant tool in the evaluation of retinal diseases such as AMD.

ABSTRACT BODY:

Purpose: To compare the agreement and repeatability between the Melbourne Rapid Fields home monitoring platform (MRF-HM) and the Humphrey Field Analyzer (HFA, Zeiss Meditec) in patients with glaucoma

Methods: One hundred patients at Moorfields Eye Hospital who have previously participated in the LiGHT trial, who have previously demonstrated stable and reliable hospital-based HVF tests in one eye, were recruited and stratified to two groups according to the severity of visual field loss. Participants were asked to perform two visual field (VF) tests with the MRF-HM using their home computer over a month. HFA data were obtained from the two most recent tests performed in the clinic. A false positive rate < 15% was the only metric used to assess reliability of the test. Test-retest variability was quantified with Bland-Altman (BA) plots and 95% Limits-of-Repeatability (LoR), calculated as the 2.5% and 97.5% quantiles of the test-retest difference, and the 95%-LoR range. Calculations were performed for pointwise sensitivity and total deviation (TD) and on the Mean Total Deviation (MTD) using the 52 locations of the 24-2 grid, excluding the two blind-spot locations. 95%-Confidence Intervals (CIs) and p-values were calculated via paired bootstrap sampling. BA plots and 95%-Limits of Agreement (LoAs) were also used to assess the agreement between all four possible MRF-HM and HFA test pairs, accounting for proportional bias.

Results: Ninety-nine patients had four reliable tests and were analyzed. The interval between the two repeat tests was 6.2 [4.4, 9.0] months for HFA and 2.14 [1.42, 3.78] weeks for MRF (Median [Interquartile range]). The 95%-LoRs and corresponding CIs are reported in Figure 1 with the BA plots. The MRF-HM had a significantly larger 95%-LoR range for all metrics compared to HFA (all $p < 0.001$). The agreement and the 95%-LoAs are shown in Figure 2. There was a significant proportional bias for all metrics (all $p < 0.001$), with the estimates from the MRF being systematically lower than HFA for more damaged VFs.

Conclusions: MRF-HM is a useful tool for home monitoring in glaucoma patients, but has a larger test-retest variability compared to HFA and the two tests are not directly interchangeable. The possibility of more frequent testing could overcome the larger test-retest variability of MRF-HM.

SUBMITTER (NAME ONLY): Mathew Palakkamanil

TITLE: The Effect of Gingko Biloba Extract (GBE) on Optic Nerve Head Perfusion Examined Using Ocular Coherence Tomography Angiography (OCT-A): A Prospective Study

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Palakkamanil, A. Zhang, C.A. Smith, O. Dyachok, L. Shuba, Ophthalmology and Visual Sciences, Dalhousie University, Halifax, Nova Scotia, CANADA|

Commercial Relationships Disclosure: Mathew Palakkamanil: Commercial Relationship: Code N (No Commercial Relationship) | Angela Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Corey Smith: Commercial Relationship: Code N (No Commercial Relationship) | Oksana Dyachok: Commercial Relationship: Code N (No Commercial Relationship) | Lesya Shuba: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the effect of gingko biloba extract (GBE) on optic nerve head perfusion examined using ocular coherence tomography angiography (OCT-A).

Methods: Six patients with a diagnosis of mild primary open angle glaucoma (POAG) were included in this study. POAG diagnosis was based on the clinical assessment, optical coherence tomography (OCT), and visual field defects using the Humphrey Field Analyzer. Patients were included if they had a mean deviation (MD) better than -10 dB, and a best corrected visual acuity (BCVA) better than or equal to 0.3 logMAR. Patients with other ocular diseases, high refractive errors, and history of glaucoma surgery were excluded. Additionally, patients with seizure disorders, on anticoagulation therapy, or on medications with possible interactions with GBE were excluded. The participants received GBE supplementation (a 120 mg soft gel twice a day) for a four-month period. All participants had baseline OCT-A optic nerve head and macula imaging performed on both eyes prior to initiation of GBE. Repeat imaging was performed after completion of the four-month course of GBE. The primary outcome of interest was the difference in perfusion density of the superficial vascular plexus of the macula and the optic nerve head annulus (adjusted by optic nerve head dimensions) before and after GBE supplementation. This study was approved by the institutional research ethic boards and was registered with ww.clinicaltrials.gov (NCT04846179).

Results: Six patients were included in the analysis which were composed of two females and four males. The average age of the participants was 69.3 years. The average baseline BCVA was 0.08 LogMAR. In post-consumption measurements, macular and optic nerve head annulus superficial vascular plexus perfusion density were not statistically significantly higher than pre-consumption measurements ($p = 0.3$ and $p = 0.5$, respectively). No significant difference was observed in post-consumption BCVA compared to baseline measurements.

Conclusions: Our study suggests that four-month supplementation with gingko biloba does not result in a significant increase in perfusion density of the macula and optic nerve head. Larger, comparative studies are needed to demonstrate the effects of GBE supplementation on ocular vascular density and glaucoma disease course.

ABSTRACT BODY:

Purpose: Clinical examination of dry eye patients may yield different results according to the examiners. We aimed to invent a fluorescence anterior segment imaging device using blue light LED (490 nm wavelength) light source and automated image processing system that analyzes acquired video images so that we can obtain a diagnostic index for dry eye by measuring the temporal change of the fluorescence signal.

Methods: We developed an anterior segment fluorescence imaging device consisting of an LED light source of 490 nm wavelength and a filter that selectively transmits only the fluorescence signal to measure the fluorescence signal change in the corneal lesion and tear film after topically applying fluorescein sodium.

In order to measure the change in the tear meniscus height (TMH), a fixed region of interest independent of eye movement was chosen and the height of tear meniscus in the region was measured.

In order to measure the tear film break-up time (TBUT), we obtained changes in fluorescence signal area in the cornea between blinking and processed the video images automatically. The point of tear film break-up was provisionally set as the point at which non-fluorescence area increased by 0.5%.

In order to measure the corneal staining score (CSS), the punctate points in the cornea that did not change in fluorescence temporally were extracted. The scoring was done according to the Oxford grading scale.

To test the reliability of the device, TMH, TBUT and CSS of 80 eyes of volunteers were measured by Keratograph 5M (OCULUS Inc., Wetzlar, Germany) and by slit-lamp biomicroscopy examined by a cornea expert.

Results: The images obtained with the newly developed device showed tear film break-up pattern, TBUT, TMH, and CSS similar to the images obtained with a video capture system in a slit-lamp biomicroscopy using cobalt-blue filter and the images obtained with keratograph 5M. The correlation coefficient showed highly reliable results for TBUT, TMH and CSS (all>0.8)

Conclusions: The LED-based anterior segment fluorescence imaging device with automatic analysis program is a useful tool for measuring dry eye indices and can yield precise results. By further applying a deep learning system, the program would even be able suggest treatment strategies.
